THE PROGNOSIS OF DIABETES IN CHILDHOOD* By PRISCILLA WHITE, M.D., BOSTON, MASS.

THE living diabetic child is one of the most outstanding medical accomplishments of the past decade. Before the discovery of insulin the mortality of diabetes in childhood was nearly 100 percent and today diabetes as a cause of death in the young has disappeared nearly to the vanishing point. The prognosis for growth and development is equally good and continued mildness and freedom from complications are assured if the disease is controlled.

The juvenile diabetic warronts special study because he has revealed new aspects of the disease. He has added new evidence for the theories of the etiology of the disease. He has yielded to the pathologist diabetes in its purest form, and to the clinician he has not only taught which complications are the result of diabetes but that their

control is within his power.

This study presents a survey of 750 juvenile patients treated at Dr. Joslen's Clinic between 1898 and October, 1931, at which time 217 were dead and 533 were living. The value of this series is increased by the relatively large numbers of long duration cases, already 76 children have survived 10 years of the disease. The course of diabetes on the long duration cases is not representative of the course of juvenile diabetes of today, but these patients do teach us what can happen to the child combating a chronic nutritional disease and how to avoid the complications of forced unnatural nutrition.

To the ctiology of diabetes the diabetic child, see believe, has made an outstanding contribution. The congenital inheritance of diabetes is evident in our scries of juvenile patients. Forty per cent of the entire series and 53 per cent of the children who have survived 10 years of the discase have hereditary or familial diabetes. The unknown cause of diabetes has stimulated investigation into the past histories of the diabetic child especially because he represents pure diabetes. The background of the adult who develops the disease is most commonly that of obesity, disease of the gall bladder or of the thyroid gland. These conditions

are exceptional in childhood and they are not found in the past histories of our juvenile patients. The common cause shared by all ages is heredity and the younger the child the greater the evidence of the hereditary taint.

Although the final proof of inheritance cannot be given for a period of years because the investigation is definitely a problem of the diabetic of today since sterility and nonviability as well as selection against diabetics in the past have lowered the possibility of hereditary cases, the family histories of the diabetic children give convineing evidence that the disease is transmitted.

Statistical requirements have been fulfilled in two methods of evaluation of the data. The first of these is based upon the comparison of the incidence of the disease in the relatives of the children compared with the expected incidence of 1 per 100 cases in the general population. The second is the more striking. It can be demonstrated that dialætes is transmitted as a simple Mendelian recessive if our diagnosis is 82 per cent efficient. That this estimate of latent and unrecognized cases is not too liberal is shown by the experimental work of Sherrill and others who have reported the great frequency of diabetic blood sugar curves in the relatives of diabetics, and because we are dealing with a young population which has not yet reached the diahetic danger zone of 50 years of age.

Certain other factars, however, must be cansidered as primary ar secandary, because heredity and environment are interrelated. These are trauma, infections, imbalance of other glands of internal secretion and overgrowth. Trauma plays na rale in the etiology of juvenile diabetes. Infections likewise are of little or no causal significance. Physical defects and infections in the past linstories of our patients have occurred with less frequency than in the average American child. Pathalagical examinations of diabetic children have fortunately been few. In the patients studied there was no evidence of organic disease of the other glands of internal secretion.

Excess of height, 2.2 inches above the Crum and Wood standard for age, has been the most common precursor of the disease in childhood oc-

^{*} Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

curring in 82 per cent of the cases for whom the data were available. The excess in height is not found consistently in all youthful age groups since it occurred in only 49 per cent of diabetic infants and 43 per cent of diabetic adolescents prior to onset. Its significance awaits the time when the pediatrician or the anthropologist can tell us whether the normal child of today is taller than the child of a generation ago.

Heredity is the one cause occurring in all age groups, infancy, childhood, adolescence, and adult life. This is very important in the control of diabetes because if we are correct the union of a diabetic with a diabetic is unwise since all the offspring will eventually have the disease. The union of a diabetic with a person who has a diabetic taint should result in equal numbers of the children developing diabetes and not developing it. When neither has diabetes, but both have a diabetic taint, then one-quarter of the children should develop the disease and three-quarters should not. If a diabetic marries a pure non-diabetic, then none of the children should have the disease.

Investigation of the carbohydrate metabolism of the juvenile diabetic is important. One of the most striking and to the casual observer the most distressing feature of juvenile diabetes is the tendency for rising fasting hyperglycemia in the successive years of the duration of the disease. This is undoubted and reported upon by all who have studied the disease in young patients and over a period of many years. It is commonly interpreted to mean that the disease is progressive in childhood,—that smaller amounts of endogenous insulin are available as time goes by. This interpretation does not take into consideration the fact that with each increment of growth more sugar is metabolized. The reservoirs for storage of glycogen, the muscles and the liver, not to mention the skin, contain some 1/28 the amount of glycogen in childhood as they do in adult life. More insulin is required for the intermediary metabolism of larger amounts of glucose. supply of endogenous insulin has not it is true kept up with the demand but there is no evidence of the progressive exhaustion of the insulin producing mechanism. That growth in body mass is one of the chief factors in the need for increasing amounts of insulin is indicated by two other facts. The adolescent diabetic, by whom we mean the patient whose diabetes started between 15 and 20 years of age, does not show this phenomenon to the same extent as the patient with onset in childhood who must grow from childhood into adolescence and from adolescence into adult life. In our group with onset in adolescence more patients had a level of the fasting blood below 200 mgs. at the end of seven years than when the disease had existed for less than 3 years. With the juvenile patients the condition was reversed-65 per cent of the patients had blood sugars below 0, 20 per

cent in the first 3 years and only 27 per cent when the diabetes had existed for 7 or more years. The chief difference between the two groups is in growth. In our diabetic pseudo dwarfs diabetes remained milder than in the patients who have grown in normal fashion.

Investigation of the fat metabolism of the juvenile patient is more fruitful than that of the adult because the child shows greater tendency toward disturbances of the fat metabolism in the greater relative incidence of coma, of xanthoma and of lipoid histiocytosis. Because of the absence of age factors he will help to solve the problem of the importance of abnormalities of fat metabolism in the etiology of degenerative processes.

In our series of 531 determinations for cholesterol on 234 children in the most recent analysis 84 per cent were below 230 which we accept as

the upper limit of normal.

The subsequent careers of patients with high and low cholesterols on repeated analysis show that of the 67 who had hypercholesterolaemia 15 per cent have developed arteriosclerosis, 6 per cent nephritis, and 4 per cent cataracts. Of the 156 who had repeated normal values of blood cholesterol 1 per cent later developed arteriosclerosis.

Extreme hypercholesterolacmia over 300 mgs. has occurred in 25 patients, 44 per cent of these

have developed degenerative changes.

Elevation of basal metabolism occurred in our series of 139 tests done on 86 patients. The amount of the average deviation was not great being +12 per cent. The greatest rise occurred at the ages of puberty, and late adolescence. Duration of diabetes had no influence upon basal metabolism. Elevation of metabolism parallelled hyperglycemia.

Although the growth and development of the juvenile diabetic of today is assured, opportunities for failure occur because we are confronted with a child who at the time of maturity has combatted a chronic disease from 25 to 95 per cent of his life and a disease in which the substances taken into the body to produce growth and the mechanism for their action is subject to interference.

The attainment of a stature which is equal to the Crum and Wood standard is the rule and the average height of the former juvenile patients who have reached 18 years is that of the average American adult stature. The weight status of our patients shows that 70 per cent are within 10 pounds of weight for height and age.

Although the assurance of growth and development have replaced the inevitability of retardation of growth and premature death diabetic pseudodwarfism exists today. Stunting from 4 to 12 inches below height for age has occurred 34 times and these cases comprise 16 per cent of the group who had onset prior to insulin and 3 per cent of

the group in whom insulin treatment from dis-

covery was possible.

Retardation of growth in the child who survived preinsulin treatment exists today because these patients were starved by their physicians in order that they might be kept alive. Retardation of growth in the child who has received insulin practically from onset of diabetes exists partly because these patients have decompensated diabetes but largely due to the fact that parents reduce the diet rather than increase the insulin in order to maintain sugar freedom. Thus, failure of growth in diabetes has one primary cause—starvation.

Sexual maturity of the diabetic child is assured. Even among our cases of long duration none of the girls who are now over 17 years of age has

failed to mature.

The choice of the partition of the diet for the diobetic young or old and its effect upon his future career is today a much debated question. The advantage of the carbohydrate equivalent of the so-called normal diet, one containing not over one-half or less than one-quarter of that amount. diets high or low in protein, and high in fat rest upon the insecure foundation which the future with its various possibilities may clarify. effect of such partitions upon the growth and development of the child, the evidence of the increased efficiency of the pancreas which results from the stimulation of diets higher in carbohydrate or from the sparing qualities of the diets lower in carbohydrate, the evidence of functional strain or damage to tissue which results when one class of foods is increased and another decreased-all must be taken into account.

The partition of our diets has been the following—from 25 to 50 per cent of the total calories are given in the form of carbohydrate, from 10 to 20 per cent are given in the form of protein and from 35 to 65 per cent are given in the form

of fat

The functions of carbohydrate do not indicote a need for great supply on the young organism. It is a readily available and economicable source of energy, a protein sparer, an antiketogen body and helps to maintain water balance. In the diabetic growth and development have occurred since insulin regardless of the ratios of carbohydrate, that is with high carbohydrate, moderate carbohydrate, or with low carbohydrate diets. In the diabetic pseudo dwarfs no constant reparation of growth in stature has occurred with any of the three dietetic methods in vogue.

The physialogical organients in favor of relatively lorge omounts of carbohydrate in the diabetic are the rate of absorption and the effect of the stimulation of carbohydrate upon the insulin producing mechanism. The rate of absorption of carbohydrate is prolonged in proportion to the amount ingested. For this reason it is argued that higher carbohydrate diets are preferable protecting the patient from hypoglycaemia.

In our experience when diets which contain from 200 to 300 grams of carbohydrate are used greater amounts of insulin are employed than when the diets contain from 100 to 200 although the increase is not proportional. Hypaglycewia from failure of absorption which is not unusual in childhood is more liable to occur when the insulin dosage is greater. Glucose, it has long been known, in periods of repeated ingestion is associated with successively lower blood sugar curves even to the level of hypoglycemia. The optimal quantity of carbohydrate to cause stimulation or the proof that this is or is not but a temporary effect is not vet established.

In our clinical experience with 100 to 200 grams of corbohydrate the disease after initial stabilization has, basing our criterion on the ratio of Carbohydrate to Insulin, becomes more severe in one-third of the cases and less severe or stationary in two-thirds, and 80 per cent of the chil-

dren have mild diabetes.

As many of the children had fasting and postprandiol and postinsulin blood sugars below 200 and 160 mgs. after five years as did the patients in whom the disease was less than 5 years' duration. Two-thirds of our routine blood sugars on children in 1931 were below 200 mgs. Fat metaholism was under even better control because 84 per cent of the most routine analyses were

below 230 mgs.

High fat diets in the normal child lead to defective absorption, excretion of calcium and retention of cholesterol. Deficiency leads to infections and rickets. In diabetes faulty utilization of fat leads to acidosis, hypercholesterolaemia, xanthona, fatty infiltration of the liver, spleen and reticulo-endothelial system, and submitimal deposition. The juvenile diabetic is often unreliable about his diet and this gives opportunities for the accidents due to faulty utilization of fat. Without insulin the higher fat diets contributed much to the management of diabetes, but with it their value has diminished.

High and low protein diets have been odvocated in diabetes. In the juvenile patient with the tendency for elevation of basal metabolism we would hesitate to prescribe an excess of protein, and because of the experience with the diabetic pseudo dwarf who resembles the protein starved child we

hesitate to give low protein diets.

With this partition of the diets 25 to 50 per cent of the calories in the form of carbohydrate, 10 to 20 per cent in the form of protein, and 35 to 60 per cent in the form of fat our children have developed normally and when the disease has been controlled have not developed complications.

Insulin treatment has been the unbroken rule in proved cases of diabetes in childhood treated at the New England Deaconess Hospital since 1923. Without it the duration of diabetes in our children was 2 years, growth in height and weight were at a standstill, and of the children who have had the disease for ten or more years that is treated at least one year without insulin, one in three of the cases studied has arteriosclerosis, one in five has cataracts, one in ten an enlarged heart, and one in thirty-five tuberculosis. With insulin the death rate from diabetes has fallen to the vanishing point. Growth in height and weight are assured and in controlled cases complications do not occur.

Insulin in its practical use is the true variable in contradistinction to the diet which is the relative constant. The actual requirement has varied from 1 to 100 units and the frequency of the in-

jection from once to four times.

The pancreas of the diabetic child shows but few irreversible changes. This is one of the chief factors which gives us the hope that eventually recovery is possible and await some future train of events. Uncontrolled diabetes in childhood is characterized morphologically by faulty distribution of glycogen in the skin, liver, muscles, and heart, and by abnormal deposition of fat in the liver, reticulo-endothelial system and blood vessels. Histo-chemical evidence of abnormal fat metabolism in uncontrolled cases is greater in the child than in the adult.

The complications of diabetes in childhood are largely diabetic coma and hypoglycemia. That the prognosis for treated coma in the young is good is evidenced by the fact that 69 of the 70 juvenile comas treated at the N. E. Deaconess Hospital since 1923 have recovered. Yet untreated coma still plays the major role in the mortality of juvenile patients who die outside of hospitals.

The incideuce of coma in the child is greater than in the adult because of the more frequent lapses of dietary control and greater susceptibility to minor systemic infections. The treatment of coma in the child differs in no way from the treatment of coma in the adult. The immediate prognosis of coma in the child is good. Nineteen per cent of the coma offenders, however, later developed complications associated with the disease.

Degenerative processes common to the adult type of diabetes may occur in children, and therefore the treatment of the disease must be directed against these sequelæ as well as toward the assurance of growth, development, and longevity. It would be tragic indeed to keep a diabetic child alive only to find that he had become crippled or blind.

Arteriosclerosis, which is now the chief enemy of the adult diabetic, has been demonstrated by clinical tests in 24 of our children during life and in six at post-mortem examination. The diagnosis was based upon the appearance of calcification of the vessels of the legs demonstrable by roentgen ray or by the retinal changes revealed by the ophthalmoscope.

Invenile arteriosclerosis as an entity among

non-diabetics is rare. Nephritis and lues, the most frequent conditions associated with premature arteriosclerosis in non-diabetics, did not appear to be contributing factors in our patients.

The feature characteristic of the living diabetic children with sclerosis is the fact that with six exceptions the onset of diabetes was prior to 1923 or prior to the general use of insulin. From this we must conclude that the probable factors which predispose to the production of the lesion in the diabetic child are the duration of the disease, the method of treatment, or its control.

That the duration of the disease is not the prime factor is evidenced by the fact that although with one exception the diagnosis of calcification was not made until after the fifth year of the disease in the living child, marked atheroma was reported by Shields Warren in one uncontrolled fatal case of juvenile diabetes even when the duration of the disease was less than one year, and three of the cases described by Naunyn and four of ours diagnosed by ophthalmoscope had had the disease for less than five years.

Hyperglycemia in varying degrees had occurred in all patients, but it is extremely difficult to evaluate its effect. A study of patients in whom the disease was of long duration shows little difference in the degree of hyperglycemia between the group who had developed arteriosclerosis and those who have failed to do so.

Chemical evidence exists that hyperlipoidemia occurred prior to the recognition of sclerosis after it had reached the stage of calcification in 75 per cent of the cases in whom analyses were made.

Although the dietary treatment of these cases has varied, it was found that of the patients for whom the data were considered reliable, clinical evidence of arteriosclerosis occurred in only three patients when the prescribed diet contained more than 110 grams of carbohydrate. Of the three patients who had evidence of sclerosis and who had received more than 110 grams of carbohydrate all had also been given excess of fat.

Excess of protein metabolites does not seem to have been a precipitating factor. There was no evidence of abnormal protein metabolism, and the protein content of the diet did not exceed 20 per cent of the total calories.

Uncontrolled decompensated diabetes was the rule in patients with arteriosclerosis. In the children whose diabetes ante-dated the discovery of insulin this could not be prevented. Disregard of diabetic routine is natural in childhood, especially when the patient becomes an adolescent, and for this reason more cases of decompensated diabetes occurred in the juvenile than in the adult series. The pathological changes in the tissues of the young diabetic in whom the disease has been uncontrolled are characterized by the faulty distribution of glycogen and fat; glycogen is absent in the normal depots, and present in tissues normally free from glycogen, and fat is demonstrable

Diagnosis

Negative

14

in tissues normally free from large amounts of fat and in some normally rich in glycogen interchange of glycogen and fat deposition may l ave been the direct or indirect cause of the degeneration which occurred in the juvenile diabetic At the present time the control of arteriosclerosis should be sought by early diagnosis and by the restoration to normal both of the nictabolism of sugar and of that of fat

Cataractous lenses not congenital in type occurred in 15 af aur diabetic children. In these patients the lenses had showers of highly refractile crystals which may or may not have been diolesterol None has been submitted to chemical

analy sis

Coma or severe ocidosis is known to have accurred in the past histories of seven of these patients, and none was a controlled case the hving coses with catorocts were markedly below standard height, and two of them are classified as pseudo-dwarfs. There is no other evidence of a deficiency disease in this group. The cataracts in two of the patients have been successfully operated upon

Peripheral neuritis, which is recognized more and more frequently in the adult diabetic, has been recognized in three of our own children

Anemia of the primary type has not accurred m aur children, although not unknown in child hood and occurring with greater frequency in our

adult patients

The presence of caratinemia, xanthama, and lanugo hair has been noted a few times in childhood cases of diabetes. With the improvement of general nutrition lanugo hair has disappeared Nanthomata have been noted three times, and in cach mstance were known to have been preceded by coma and hypercholesterolemia The xanthorntous lesions have disappeared when the fat in the diet has been reduced. Coincidently the cholesterol of the blood has fallen the selective food habits of the child carotinemia occurs frequently, and can be made to disappear when the vegetables which are rich in carotin are withdrawn from the diet.

Infections of the skin have been not infrequent, and may occur as in the adult at the time when the disease is uncontrolled. Abscesses carbuncles, and furuncles have occurred in at least 27 of our juvenile diabetics and all made a good recovery following surgical or non surgical treatment as

Susceptibility to tuberculosis depends upon the general prevalence of the disease and upon ex-We knew eight of our children have active pulmonary tuberculosis, and in six instances there was a definite history of exposure to the diseasc

The frequency of a positive tuberculin test is somewhat greater in our group than the average We have tested 75 children For all ages the number of positive reactions was 41 per cent

This was the same ratio as that which was found in the Pirquet chaic

Iwo hundred and thirty-seven routine X-ray examinations of the chests of diabetic children have been done by Dr I K Bogan, working with Di L B Morrison at the New England Deaconess Hospital

> TABLE Per Cent

9 f rachiobronchial adenitis 65 Trachobronchial-adentis with calcification ... 11 Suspicions ١ Acute

Acute infectious diseases accurring in childhood are not more severe when they occur in the course of diabetes, but they cause temporary loss of tolerance Glycogen is improperly stored and the danger of coma is imminent

The contribution of the juvenile diabetic to surgery has been to give confidence to the surgeon and to the chaician since this severest type of diabetic has withstood surgical procedures so well Seventy operations have been performed on juvemile diabetics at the New England Deaconess Hospital between 1924 and 193f and without a single fatalits

The care of the diabetic child resolves itself mainly into three factors, first, the maintenance of the normal physiological processes of the grow ing and developing organism, second, the preven tion of the accidents of diabetes, and third, the eventual production of an individual who will be

an economic and a social asset

Heredity and overgrowth are the most common precursors of the disease in childhood tions were unusual Thirty of 84 infants had never had an infection prior to onset of diabetes Although the number of children handicapped by diabetes is at present not large, we estimate there are some 10000 such children in the United States, one thousand new cases are recognized

Fasting hypergly cenna has been mare frequent in successive years of the duration of the discase, but the element of growth may be the cause rather than progression of the disease tabolism is normal when the disease is controlled Fifty-six per cent of the cases with high cholesterol values have later developed complications and in 44 per cent they were degenerative, namely cataracts, calcified vessels or xanthoma The respiratory metabolism is essentially normal except when marked gly cosuma, hy pergly cemia, or acidosis are present

The potentiality of growth in the diabetic child is gard because at the onset of diabetes his stature is in excess of the standard average Retardation of growth and failure of development were

associated with forced undernutrition. Establishment of normal growth and development followed the use of insulin and of the subsequent normal utilization of a diet adequate in calories.

The selection of the diet high in carbohydrate, moderate in carbohydrate or high in fat varies according to whether one believes that increased efficiency of the pancreas results from the stimulation of diets higher in carbohydrate or from the sparing action upon the pancreas or diets which are lower in carbohydrate. Diets with excess of calories and those high in fat are to be avoided, because overnutrition is the most common precursor of diabetes in the adult, and because a large amount of fat improperly utilized is a possible, even probable, precursor of degenerative processes.

The chief complications of diabetes in child-hood are diabetic coma and hyperglycemia. If untreated they may prove fatal. Degenerative processes usually associated with age occur in the child, for already 24 of our diabetic children are known to have peripheral sclerosis, and 15 have cataracts, but these have occurred only in patients whose diabetes was of long duration and in whom undernutrition or forced unnatural nutrition without insulin, or diabetic decompensation have played a part.

The pathology of the juvenile diabetic is characterized far more frequently than in the adult

by the absence of irreversible changes in the paucreas, giving us hope for the future of the diabetic child. Uncontrolled diabetes is associated with deposition of glycogen and fat in abnormal fashion or in tissues normally free from them.

Protection of the diabetic child against his social environment is fully as important as profection against high physical environment. First, he must be protected against discouragement by being shown that he can lead a normal life. Outstanding work of every sort has been done by adult diabetics, and the child at onset of his disease is characterized by mental precocity; this persists even if physical precocity wanes.

Second, in the adolescent period the child may decide to lead a short life and a merry one, and he must be protected against its dangers. His family must expect him to be no better and no worse than the other children. Diet breaking should not be made a moral issue. Promises which may not be followed must not be exacted, and above all neither the family nor the physician must place the child in a position where he is almost forced to cheat, steal, and lie to maintain his existence.

The goal of treatment today is no longer just the living diabetic child, but the child characterized by honesty and intelligence, physical proportion, endurance, happiness, and freedom from the complications of his disease.

Discussion: Dr. John R. Williams: Dr. White's paper is an important contribution to the subject of diabetes in children.

The general experience substantiates the conclusion that heredity and overweight are common precursors of the disease and that infections are rarely a factor. It is my experience that high blood sugars and sugar in the urine are a constant phenomena in the diabetes of childhood. It may sound like a heresy to say so, but I have not observed that either of these abnormal physiological states are very harmful.

It would seem to me that the only experience of value in judging the diabetic state is that based on cases that have lived for years. In an analysis of a large group of children that have passed through our clinic I have selected 50 patients who have had diabetes for many years and on whom we have fairly complete information. Several of these children were preinsulin cases. All of them have had diabetes more than three years and several of them for more than ten years. Practically every one of them carries a fairly constant high blood sugar and as a rule has sugar in the urine. They have all grown at the normal rate; some of them have developed excessively. To the

casual observer they are well. My explanation of the well-being of these children is that they are only diabetic part of the day; that is to say, for certain hours of the day the insulin makes them practically normal, and other hours in the day they have diabetes. An individual who passes not more than 5 to 10 grams of sugar in the urine each day has many hours when his urine will be sugar free and his blood sugar normal. Such an individual apparently is not harmed by the disease. He will rarely exhibit clinical evidence of diabetes.

I do not believe in the under-nutrition of any diabetic. As a class our diabetic children are as strong as are normal children. Our experience coincides with that of Dr. White with reference to complications; namely that coma and insulin reactions are the most common and one has to be on the alert to distinguish between diabetic coma, which may come from neglect on the part of the parent, or the coma of hypoglycemia due to insulin overdosage. I have seen no reason for believing that the pancreas recovers or that the function of the Islets of Langerhans is increased. For the past three or four years we have applied the insulin coefficient method of evaluating the patient's clinical condition. This method may not be mathematically exact to the unit but I am satisfied that it is far more accurate than any other in use and that when tests are properly carried out and correctly interpreted it is possible to say very difinitely whether or not a patient is improving or failing. I mean by the insulin coefficient the maximum amount of in sulm that a patient may make in a day. The normal child can make an almost unlimited amount of insulin but usually requires for his duly food from 100 to 150 units. A severe diabetic is one who can make not make than 20. but usually less in a day. In the fifty cases studied the insulin coefficient has ranged from 2 to 44 units. Under the most careful supervision it rarely increases One patient a boy who has been under my eare for twelve years and whom I first saw at the age of seven, now nineteen years of ago, and who has had a trained worker with him ever since, had an insulin coefficient of 27 at the onset of his dis He, of course, has had many ups and downs since, including coma. He began taking insulin at the age of 10 when his coefficient was 23 At the age of nineteen his coefficient is now 30. In the early stages lie took 20 units of insulin a day He is now taking 26 on a diet which contains 150 grams of carboliy drate and vields 230 grams of glucose. This patient is perlans the best studied one in my scries Io summarize, in 29 of the 50 cases there is a positive coefficient. In 17 the amount is so small and the difficulty in balancing it is so great that the coefficient is a negative factor At the beginning of the treatment 40 of these children had a positive coefficient nine of them a negative coefficient In 13 there has been a slight increase in the insulin co efficient, in 25 cases there has been a decrease, and in 12 there has been practically no change I regard these figures as of the highest importance in determining the prognosis of diabetes in childhood. They mean that a diabetic child may stay alive, grow and be practically well and normal with a reasonable amount of care and adjustment even though the pancreatic function does not improve The function of the pincrens changes very little if any on the positive side and may fail if the child is denied proper care Undernutrition is almost as bad as no treatment at all for the diabetic child I belive they should be well fed and given enough insulin to take care of the food. I have seen severe diabetic children grow from early ehildhood, from kindergarten through college, and marry, with but very slight handicap

The Society is indebted to Dr White for a

very valuable paper

PAINFUL SHOULDER

Its Diagnosis and Treatment

By CHARLTON WALLACE, MD, NEW YORK, N. Y

BLIORL entering upon the discussion of the various conditions pain of the shoulder or deltoid region, it might be well to refresh one's memory about some of the most salient anatomical parts Some points of the innervation should be mentioned, so that proper identification of the in dividual structures may be recognized, thus avoiding confusion in diagnosis

The cap of the shoulder is of course covered by skin, subcutaneous tissue and a prominent muscle, the deltoid The other muscles cross ing the joint which should be remembered are the supraspinitus infraspinitus, subscapularis biceps coracobrachialis, latissimus dorsi teres major and minor triceps, and pectoralis major and minor In the average developed person, felt immediately under the deltoid is the bony dome comprising the acromial end of the clavicle and the acromial process of the scapula Extending inwardly from this point is found the outer third of the clavicle and posteriorly,

*Real at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y May 25 1932

the spine of the scapula. About one meh and one quarter from the extreme tip of the aero mial end of the clavicle, is the subclavicular triangle in which the coracoid process may be felt on deep pressure. The most external bony prominence felt immediately beneath the acromial process is the greater tuberosity of the humerus and just anterior and internal to it hes the lesser tuberosity Between these tu berosities is the suleus or groove carrying the long head of the biceps. The head of the hu merus may be palpated at the posterior margin of the deltoid by adducting the arm across the chest to the mid-line of the trunk, while the elbon is in flexion The capsular ligament, the acronio elavicular ligament, the synovial lining of the joint, the subacromial subscapular infraspinatus and subcoracoid biirsae are of importance

The irritation of the articular filaments from the circumflex and suprascapular nerves supplying the joint would account for the pain there The supply of the integument over the shoulder and the back and lower part of the neck is from the three branches of the supraclavicular nerve, which comes from the third and fourth anterior cervical roots. In conjunction with this origin, the phrenic nerve arises chiefly from the fourth cervical receiving an offshoot from the third and fifth cervical, sending twigs to the pericardium and pleura, through the diaphragm to its inferior surface, to the coeliac plexis, the peritoneal ligament of the liver, the suprarenal glands, the inferior vena cava, the cystic duct and the neck of the gall bladder.

This ramification of the filaments from the supraclavicular and phrenic nerves should explain many of the pains around the shoulder, when there is no altered structural condition in the region to warrant even discomfort.

The remote visceral, thoracic conditions, which may be instrumental in causing referred pain around the shoulder are: angina pectoris, aortic atheroma, aneurism, pleurisy, pneumonia, pulmonary tuberculosis, pneumothorax, intrathoracic new growths; and the abdominal ones are: gastritis, gastric ulcer, carcinoma, catarrhal duodenitis, ulcer of the duodenum, gallstones, colacystitis, nutmeg liver, acute hepatitis, hepatic abscess, subphrenic abscess, effusions into the peritoneal cavity or intraperitoneal extravasation of blood pressing upon the diaphragm. When the foregoing lesions cause no actual pathology around the shoulder, the pains are solely from the phrenic nerve; then, no physical therapeutic measures for treatment of the shoulder are indicated. The relief of the original condition abolishes the pain.

The other better-known, purely reflex pains to the shoulder are affections of the neck such as cervical tuberculosis, fracture of the third, fourth, or fifth cervical vertebrae, simple periarthritis due to strain compressing the nerve roots and myositis of the deep muscles of the neck about the same level.

The successful treatment of Pott's disease relieves the pain. General and local ultraviolet irradiation are beneficial.

After the fractures of the cervical vertebrae need no longer the recumbency and fixation in hyperextension treatment, then superficial heat and diathermy are used.

Pain of the shoulder emanating from the base of the neck, often attributed to a neuritis, is seldom actually an inflammation of the nerve but more frequently, comes from muscular affection. One should be careful in arriving at a correct diagnosis before prescribing. Heat, deep massage and diathermy are most helpful. Myositis of the trapezius muscle due either to a tear or indurations from autointoxication, is one of the most frequent causes of reflex pain to the shoulder.

Neuritis of the suprascapular nerve usually can be diagnosed by pressure over the upper margin of the supraspinatus muscle in the triangle formed by the superior border of the scapula and the upper margin of its spine. Inflammation of the circumflex nerve can be localized by making pressure posteriorly against the humerus between the quadrilateral space formed by the teres major, minor and the long head of the triceps muscle. Patients with inflammation of the nerve sheath are generally so sensitive, that the slightest palpation upon these nerves causes excruciating agony. The treatment of acute neuritis is rest, constant heat either moist or dry, and hypodermic injections of morphine, near but not into the nerve, for the first day or two. Pyramidon, seven grain doses internally, is highly recommended as an anodyne. Heat from a large candle power lamp, Oudin current, static sparks or galvanism, should be tried and the agency giving the greatest relief is the one to use in the subacute stage.

Uncomfortable, aching or painful conditions accompanied by definite lesions immediately in the joint neighborhood are due either to local bone disease, remote infection or injury. careful history of the duration of the complaint, previous illness, a pre-existing or present focus of infection should always be sought, when there has been no trauma. is only rational to eliminate such foci, as pyorrhea, decayed or abscessed teeth, sinusitis, infected tonsils, or a definite focus of infection elsewhere, which may be a primary etiological factor of the symptom under consideration, before one should expect physical therapeutic agencies to have real curative effects. Even when the focus of infection has been eliminated, the local pathological condition causing the distress may persist for months thereafter.

Acute osteomyelitis of the head and neck of the humerus requires immediate surgical operation. Tuberculosis in the same locality is treated conservatively. Either condition should have the arm placed at an angle of 45 degrees from the trunk line. The identification of the bone lesion is made by the clinical symptoms and signs aided by x-ray findings. Proper treatment of osteomyelitis and tuberculosis of the shoulder usually relieves the pain.

Many cases of myositis, bursitis, synovitis, arthritis, periarthritis, tendonitis, and neuritis have demonstrated, that a toxic condition elsewhere was behind the lesion or pain. A diagnosis, which one of last mentioned conditions exist, although not always easy, is valuable before treatment is undertaken.

The diagnosis of a muscular inflammation can be definitely made by superficially or

deeply palpating over the area. Anointing the surface to be so examined with vaseline facilitates feeling indurations or lumps.

In acute myositis, heat and gentle massage may secure relief but in the subacute with long standing indurations, the massage of necessity must be very hard and is frequently painful to the patient. In the latter type, the treatment extends over a prolonged period. The muscles most often involved here are trapezius, supraspinatus and deltoid.

Bursitis, whether of infectious or traumatic origin, also responds readily to physical therapy. The diagnosis, when the subdeltoid bursa is the one involved, is not so difficult. The diagnosis may or may not be aided by x-ray findings. The so-called soft x-ray very often will pick up the swollen bursa even if there are no calcareous deposits therein. In the acute stage, where there is considerable distention of the bursa, one may see on inspection a swelling at the anterior margin of the deltoid just beneath the acromial process. As a rule, the examination is made with the patient's arms by the side and a comparison of the two shoulders is observed. Voluntary abduction of the arm is very painful and restricted. An important sign with us is to have the patient, with the elbow flexed, try to put the dorsum of his hand to his back. In this movement, the hand will only reach to about the level of the sacrum or the lower lumbar region. Inward rotation is greatly restricted. During the acute stage, rest of the shoulder, the arm in a sling, a tight crisscross adhesive plaster bandage forming a cap for the shoulder and licat by either the electrical pad or hot water bottle, for the first two or three days, have given relief. The abduetion method of tying the hand to the head of the bed has never been used by me. After the first few days, the bandage may be omitted and heat and diathermy instituted. The same physical therapy treatment is indicated for the subacute affection. I can recall no case of bursitis during the past fourteen years, that has not pleasantly responded to the foregoing method of treatment. We purposely are avoiding the academic discussion of whether or not this swollen bursal sac is originally a tendonitis of the supraspinatus tendon or a bursitis per se, although one leans towards the latter. In my experience, it has never been found necessary to operate for this condition.

Synovitis of the shoulder joint is seldom seen unless accompanied with arthritis. Arthritis may be either acute, subacute, or chronic. It may be due to a rheumatic or toxic condition or constant slight trauma by over-use of the arm. It has not been my experience to have seen a purulent arthritis of this joint. When such exists, naturally prompt surgical

measures are indicated. For the subacute and chronic types of arthritis, whether traumatic or infectious, the symptoms may be a constant ache, stiffness within the shoulder joint and pain on attempt at motion in any direction. The muscle spasm encourages the scapula to move with the shoulder joint. There is muscular wasting dependent entirely upon the duration of the disease. Rotation is generally more painful than abduction. The x-ray may demonstrate an osteoperosis of the upper end of the humerus. As these patients generally carry their arms by their sides over a prolonged period, they may be treated by using an abduction splint and given heat and massage for the superficial muscles and tissues and diathermy through the joint. It is also advisable to give the joint passive motion of abduction and rotation to the range of these movements, which the patient can stand. Many times it is advantageous to give these patients a general anesthetic and forcibly break up the adhesions in or around the joint It often is necessary to repeat these manipulations several times before a satisfactory range of movement has been obtained. The forementioned physical therapy measures should be applied during the intervals between and after the operations.

Tendonitis, whether due to inflammation or traumatic condition, is one of the most difficult conditions to diagnose and usually the symptom of pain is manifested when the muscle tendon is put upon a stretch or strain. However, when the tendon sheath of the long lead of the biceps is involved, it is accompanied with disability to this muscle and definite localized pain, on pressure, along its groove between the two tuberosities. Rest with the arm in a sling, heat and diathermy are indicated.

Anterior poliomyelitis during the acute stage, when the shoulder muscles are paralyzed, creates severe pain over a limited period. An airplane splint and heat should be prescribed.

When pain is eaused by an injury, physical therapy measures are of inestimable value in relieving pain of the shoulder, preventing disabilities and restoring function.

The traumatism about the shoulder may be divided into those caused by major and minor accidents.

In the major group, are the well-known fractures of the head of the humerus, surgical or anatomical neck of the humerus, the greater tuberosity, fracture through the epiphyseal line of the head, fracture of the neck of the glenoid, fracture of the aeromial process and fracture of the iunction and outer third of the clavicle. These fractures may be caused by direct or indirect violence. Given a history

of the type of injury, with immediate excruciating pain and disability, accompanied by swelling, ecchymosis and dissolution of continuity, one should immediately suspect a fracture. Since the advent of the x-ray, which definitely assists in making a diagnosis, it is preferable not to attempt eliciting crepitation; because the movements of the fragments and the resisting spasm of the muscles may do untold damage to the surrounding soft parts. First-aid splints should be applied and all handling or manipulation of the injured part should be avoided during transportation of the patient. In the forementioned fractures of the upper end of the humerus, when a correct diagnosis and the relation of the fragments one to another have been determined satisfactorily, one has the choice of treating these fractures with the Balkan frame traction splint and mobilization method; or with immobilization of the part. Some of us prefer reducing these fractures under a general or local anesthetic and applying an abduction plaster Paris spica bandage sometimes combined with traction underneath the bandage. If the pain in the shoulder persists for forty-eight or seventy-two hours after the bone has been set, it is, in all likelihood, an indication that the fragments are not in proper approximation. One should not wait for this symptom; but have an x-ray taken immediately after the setting of the fragments. Fluoroscopic observations while working on the fracture are most helpful. These fracture patients should be kept in bed until union has taken place. The weight of gravity and the drag of the arm very often interfere with proper healing. The determination when good union has taken place is an important feature, so that physical therapy treatments and the restoration of function can be started at the earliest possible time. duration of the period of the bandage, treatment of the fracture itself, is variable; because of idiosyncrasies of patients to heal rapidly or slowly. Heat, massage, passive and active motion administered immediately after the dressings are removed, aid in diminishing the pain around the joint and obviating disabilities. These treatments are essential in adult patients in order to hasten full range of comfortable movements. The older the patient, the more important are these remedial agencies.

The peculiar conformation of the bones comprising the shoulder joint and the looseness of its capsular ligament permit motion in all directions. It is a universal joint. The pectoralis major, anterior fibers of the deltoid, the coraco-brachialis and biceps muscle, when the elbow is flexed, move the arm forward; the latissimus dorsi, teres major, posterior fibers of the deltoid and the triceps, when the forearm

is extended, take the arm backward. The deltoid and supraspinatus muscles abduct or elevate the arm; the subscapularis, pectoralis major, latissimus dorsi and teres major adduct the arm. The infraspinatus and teres minor are the external rotators; the subscapularis, latissimus dorsi, teres major and pectoralis major are the internal rotators of the joint. The definite understanding of the actions of these individual muscles aid materially in diagnosing any pathology taking place within them.

True luxation of the shoulder is another major traumatic cause of excruciating pain and sudden disability of the joint. The diagnosis is based on the head not being in its normal position, felt in a strange locality and the contour of the injured shoulder, as compared with its fellow, is quite abnormal. X-rays clinch the diagnosis. The surgical treatment is reduction under a general anesthetic. When this has been accomplished, the abduction attitude of the arm is more desirable than having it adducted and close to the trunk. Abduction prevents formation of tight adhesions of and around the capsule as well as contractures of the muscles. These are quite likely to occur in patients over thirty-five years of age. position of abduction should also prevent recurring false dislocations or subluxations. current dislocation of the shoulder is quite painful and disabling and happens with some particular athletic endeavor and muscular movement. Since the Nicola operation has been devised, there is no question about the cure of recurrent dislocation of the shoulder without loss of function to the joint. Dislocations are greatly benefited by heat, massage, controlled passive and active movements, when the splints have been removed.

The minor injuries causing pain in the shoulder that are not totally disabling, are usually seen in athletes or middle-aged people, who go in for some form of exercise to which they are not accustomed. There may be a stretching of the tendon or a tear of the muscle fibers, very slight in the beginning and the pain insignificant; but the repetition of the exercise increases the pain and disables the patient for that form of muscular activity. Baseball and football players are the class of people most frequently affected. The deltoid supraspinatus, biceps tendon, latissimus dorsi, teres major, pectoralis major or subscapularis are the muscles often strained or bruised. When the pathology is in the muscular fiber, there is pain on pressure over the localized spot, as well as increased pain, when the action of this individual muscle is brought into play. the tendon or muscle attachment is involved, the ascertaining of the pain on palpation is not easy; but the aggravation of it by the physiological action of the special muscle, should aid in the diagnosis. Superficial heat, massage and diathermy are very beneficial; at the same time, the particular form of exercise causing the pain should be stopped in order to avoid irritation.

A bursitis or periarthritis may occur in the

same manner. The treatment of these has already been mentioned.

Conclusions — Physical therapy has proven its worth in the treatment of shoulder pain. Accurate diagnosis is essential before it should be instituted. The recovery of properly treated surgical shoulder cases is hastened by its use.

Discussion - P. L. Firster, M.D., Albany, N. Y.: Dr. Wallace has presented us with an unusually complete review of this very important subject, considering the briefness of the time at his disposal. It seems to me that the great lesson to be drawn from his paper is not the acquisition of knowledge with reference to any particular operative technique or in learning what special modality is to be used in any specific instance of pain in the shoulder, but rather the realization that we have at our disposal a means of treatment for which a great many people would have reason to be grateful if we but used these means when indicated.

The orthopedic surgeon, of course, has a decided advantage. By the time a patient reaches his office, that patient is quite prepared for an operation or a stretching or some other such radical procedure. He has already run the gamut of general practitioners and, not having been relieved, he is ready for more drastic measures. The general practitioner, having physical therapy at his command, can, by judicious application, prevent a great many operations and can do an untold amount of good, saving his patients not only a good deal of time and suffering, but a good deal of money as well.

I am glad Dr. Wallace emphasized the inportance of making a proper diagnosis. It is quite obvious that physical therapy measures applied to a shoulder for relief of pain in that joint can be of no earthly avail if that pain is merely referred, the pathology actually being in some nearby organ. It is equally obvious that it is this sort of misdirected effort which has been responsible to a large extent for the disrepute in which physical therapy was held not so very many years ago. I have frequently heard Dr. Kovacs stress the point that if physical therapy treatments produced no tangible results within a period of two or three months at the outside, then it is safe to assume that either the treatments are improperly given or else there has been an error in diagnosis-the latter being the more probable.

EOSINOPHILIA IN BACTERIAL REACTION SITES

Preliminary Report

By MAXIMIN D. TOUART, M.D., NEW YORK, WILLIAM S. THOMAS, M.D., NEW YORK, and HOLLIS K. RUSSELL, M.D., VALHALLA, N. Y.

Grasslands Hospital.

From the Grasslands Hospital, Valhalla, Westchester County, N. Y., and the St. Luke's Hospital, New York City.

OSINOPHILIA has come to be considered as a regularly occurring feature of allergie states. Cooket looks upon local eosinophilia in the respiratory tract in cases of infective asthma, as evidence of the presence of allergy. He feels, however, that a mechanism different from atopy is at work in the asthma that is due to bacteria. Kline, Cohen and Rudolph2 recently reviewed the literature relating to tissue eosinophilia and reported their own observations of the occurrence of eosinophilia in wheals resulting from the injection of various materials and from the effects of physical agents. They reported a great predominance of eosinophilic cells in the wheals observed (whatever their cause may have been) in allergically sensitive individuals. They noted the incidence of 10%, 8% and 17% of eosinophilia in three reaction sites which had been excised after the lapse of 22 hours from the time of injection. No control sites were examined so that an accurate comparison of their findings with those presented herewith cannot be made. Eosinophilia in wheal reactions to pollens and to other atopens is receiving the attention of British workers.³

So far as we are aware, no reports have been published on the presence or absence of eosino-philia in the wheals and late skin reaction sites produced by the injection of bacterial products. It is our purpose here to make a preliminary report of the incidence of local eosinophilia observed in a small number of such reaction sites.

Cell material for examination was obtained from reaction sites and was prepared, stained and counted as in an ordinary different leucocyte count. After experimentation the following method for obtaining the fluid contents of skin reaction sites was adopted: a small superficial incision is made into the reaction site not any

more deeply than is necessary to permit the escape of a drop of blood and lymph. Gentle suction by means of a Bier's hyperemia cup enhances the flow if necessary. The first drop appearing is smeared upon a microscopic slide and stained within a few hours. A control drop is obtained from normal skin of the patient at the same time and is examined in the same manner.

Autogenous vaccines, old tuberculin and diphtheria toxin were injected into the skin in 22 cases. The subjects were both adults and children and were selected at random from a large number of patients. The accompanying table shows the collected data and the results of examination of the smears. No attempt was made to differentiate the cells further than into the two classes of eosinophiles and non-eosinophiles.

It will be seen that positive reaction sites, both early and late, show, in most cases, the presence of eosinophilia in excess of that present in the normal sites. The positive tuberculin reaction sites, with one exception, and the Schick reaction site. examined so late as the 5th day, ex

hibited increased eosinophile cell contents as compared with the normal skin sites, although in less degree than in some other cases.

The absence of eosinophilia on three occasions, two in the case of T. S. W. and one with the patient A. C., offer ground for speculation and show the desirability for further research. A. C., previous to this examination had been relieved of an ulcerative colitis of three years' duration after a short course of autogenous vaccine treatment and was, perhaps, at the time of testing, in a non-allergie condition.

COMMENT

Should the findings of this small series of cases be corroborated by future investigations, eosinophilia will be recognized as being a regular feature of positive early and late reactions to intrader-mal injections of bacterial products. Insofar as eosinophilia indicates the presence of hypersensitiveness, it would appear that the early wheal and the late local reaction are but two manifestations of the same underlying condition, namely, bacterial 'hypersensitiveness.

2 Kline, B. S., Cohen, M. B., and Rudolph, J. A .:

The cellular contents of sites of other types of skin reactions and modifications of technic in examining them are being studied. It is hoped that this study may throw light on the question of the origin and properties of eosinophiles and other cells from the tissues which participate in immunologie processes.

SUMMARY AND CONCLUSIONS

A record is here presented of an investigation into the incidence of local eosinophilia at the sites of early and late skin reactions following the intradermal injection of bacterial substances.

An increase at such reaction sites in the percentage of cosinophile cells in the fluid contents over that found in normal skin, is shown to be present in most of the patients examined.

Mention is made of other directions in which the present research may be directed. It is suggested that corroboration of these findings in a large series of cases will judicate that the typical skin reactions produced by the injection of bacterial products are distinctly allergic in their nature.

STUDIES IN THE SERUM TREATMENT OF PNEUMONIA* By JESSE G. M. BULLOWA, M.D., NEW YORK, N. Y.

From the Littauer Pneumonia Research Fund of New York University, Harlem Hospital Station, and the Medical Service, Harlem Hospital (Department of Hospitals), New York City.

THE results of serum treatment in pneumococcus Type I pneumonia have been so satisfactory in the hospitals where it has been extensively employed that it is desirable that physicians should adopt it in hospital and in private practice. The results from its proper use are as definite as those obtained with any other therapeutic serum, and, in the treatment of pneumonia, more effective than any measure hitherto recommended.

Distribution of Types. At Harlem Hospital during the past four seasons Type I cases have occurred in about 25 per cent of all adult pneumococcus pneumonias; of each Type II and Type III; approximately 10 per cent were found. The appearance of organisms formerly included in Group IV, and now classified as separate types through the efforts of and in accordance with the elassification of Georgia Cooper of the Resarch Laboratory of the Department of Health, New

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N Y., May 25, 1932

York City, has been studied and some interesting facts are revealed. The miscellaneous or "x" group, which originally constituted the major portion of our cases, has been gradually reduced. During the past season, only slightly over 1 per cent of all the pneumococci recovered were in that group. Only 3 pneumococci which did not fit into the classification of pneumococci up to Type XXXII were found among 253 cases.

Certain types, notably Type IV and VII, seem to be quite important; in fact, in some years they are more important than is Type III. Some are apparently occurring with increasing relative frequency, as Types IX, XIV, XVIII and XXI.

Type V was formerly, in some cases, included with Type II. It was originally known as the sub-type IIa of Avery. Type VIII was formerly often included with Type III. It was necessary to separate them because they are different types and require different serums. Clinically, the diseases they cause differ from, and have a prognosis differing from pneumonias due to Type II and

111 05

Type III with which they were confused. Useful sera have been prepared for fourteen types other than Types I and II, and are available commer-

cially for Type VII and Type VIII.

Type XIV and Type VI, which seem to be becoming more common among adults, are among the most frequent invaders of children. This year Type XXII has appeared in six cases and in the future it may be an important type. What shall the future reveal in connection with laws governing the appearance and disappearance of these types? What their importance is to be, and how they are to be combatted remains a problem. Possibly we may have warning from studies such as these so that in anticipation of epidemics, specific sera can be prepared, or ferment organisms can be secured.

Multiple Infections: It is of both practical and theoretical interest that among 1,601 cases, 56 were multiple pneumococcus infections. In some cases, the invasion was simultaneous, in some consecutive. It is probable that, in some cases, one of the organisms recovered was merely carried and without responsibility for disease. This 3 per cent occurrence of multiple invasions may account for some apparent serum failures because in such cases the serum used was not specific for the organism responsible for the illness.

The fact that almost 40 per cent of cases are Type I and Type II supports the view that good practice would be to give Type I and Type II serum to all cases pending the determination of type, as almost one-half the cases might then be

favorably influenced.

Results with Type I and Type II Serum: What are the results with serum in pneumonias due to pneumococcus Type I and Type II? At Harlem Hospital, in the order of admission alternate cases are given serum. All cases in which Type I is discovered to be the invader are given Type I serum, for proof of its efficacy has already been provided. Other types are still alternately placed in the serum and non-serum groups of their respective types. On this account, since 1929 few cases of Type I, unless they are moribund or post-critical either on admission or when the Type I is discovered, are not given serum. It is interesting to observe that in the small group of 53 cases treated without serum, the mortality of bacteriemic and non-bacteriemic cases is that usually encountered by most observers in hospital practice without serum, or 30 per cent. Eight of 10 positive blood culture cases died, or 80 per cent.

The success of treatment depends upon the correctness of typing and also upon the strength of serum, the medical and surgical care, the nursing, the occurrence of synchronous infections, and other factors, some unknown.

Studying the Type I experience we find some variation in the mortality rate from year to year, but in no year did the mortality in treated cases

reach that attained in untreated cases. The reduction in mortality was especially noticeable in the bacteriemic cases; it is 45 per cent less than the usual fatality rate. For three of the four years the mortality was in the vicinity of 13 per cent, which means that only 1 patient in 8, instead of 1 in 3 or 4, died, as would have happened if the ordinary fatality rate had been maintained. The year with the high rate, 21 per cent, was also the one in which our Type II results were least favorable. During the past four years the mortality in 309 serum cases was 49, or 16 per cent. Among 96 blood invaded cases, 37 died, or 39 per cent.

It is noteworthy that the admission cases, or those receiving serum without delay to determine the type, showed a lower mortality. Though the difference in the mortality rate in the two groups is 4 per cent, this is a percentile difference of 22

per cent.

TABLE 1

Type 1-July, 1928, to March, 1932-363 cases

Cases receiving no serum, bacto- riemic and non- bactericmic	when	es of e dmission ing seri	n,	inel	receivi after del dent to yping		t	l serum reated cases	
Total Cases Deaths % 54 16 29	Total Cases lot	Deaths 21	7,0 14	Total Cases 141	Deaths 25	50	Total Cases 309	Deaths	70 16
Bacteriemic cases 10 8 80	43	16	37	53	21	39	96	37	39

It requires less serum to prevent invasion of the blood stream than to sterilize it after invasion has occurred. Until type is determined, patients are not vigorously treated. On this account, it is desirable that producers prepare and market serum of higher titre so that the initial doses may be greater than at present—15,000 units for the first dose and 30,000 to 40,000 units for subsequent doses.

In compiling these statistics, no cases have been omitted because they have come in with pulmonary edema, or because death has occurred from subsequent surgical operation, or other complication.

The reduction of the total Type I mortality to 16 per cent in a group of 309 cases in which all cases admitted are included, is a reduction of mortality of approximately 50 per cent. If only cases which had been in the hospital more than 24 hours had been included the results might have been even more striking.

The Type II cases merit study. In these cases we have strong suggestive evidence that the serum for Type II is of value if given in sufficiently large doses and promptly. There is a distinct reduction in mortality over the entire period, which happens to be more marked in cases treated on admission with Type I and Type II serum.

The very high mortality among the blood invaded patients and the relatively poor results in this group shows the importance of prompt and adequate administration of serum before the defense mechanisms are exhausted.

One hundred and sixty cases were treated in three and three-quarters years. Of 84 without serum, 36 died, or 43 per cent; 35 were bloodinvaded, and of these, 27 died, or 77 per cent. Fifty cases received serum on admission; 11 died, or 22 per cent. Twelve were blood-invaded and 8 died, or 67 per cent. Twenty-six received serum when the type was determined; 12 died, or 46 per cent. Of these, 14 were bacteriemic; 10 died, or 71 per cent. In all, 76 cases received serum; 23 died, or 30 per cent. Included in these 76 cases were 26 bacteriemias; 18 died, or 69 per cent.

Let us return to Type I. I have analyzed the results of serum treatment in Type I for 1929-30 and 1930-31 in respect to certain points.

Prior to the season of 1929-30 we gave the refined serum every eight hours in a dose comparable to that used by Cole in his studies. At this time, cases usually terminated 48 hours or more after commencement of serum. In a study of the cases treated during 1929-31, certain facts are observable. 20,000 units of serum or more was given every three or four hours. Cases were considered terminated when the temperature remained below 100°; usually at that time the pulse was less than 90. Among the non-bacteriemic cases, most cases terminated on the 1st and 2nd day; 81 out of 123. Termination of the bacteriemic cases frequently occurred on the 1st or 2nd day; 14 out of 33 who recovered. The majority-19-required three days or longer to reach normal. The deaths in the bacteriemic cases were usually on the 1st or 2nd day of treatment. It was also . observed that among cases terminating early the crisis occurred, in the majority of cases, before the 6th day, and in cases requiring two days for treatment it was before the 7th day. This is at least two days earlier than customary. It was observed, too, that the cases requiring prolonged treatment were usually cases with a bacteriemia.

Of course, such prolonged treatment in some cases required large amounts of serum, and it might be asked whether the result was worth the

expense and effort. Aniong 10 bacteriemic cases receiving more than 300,000 units, 4 recovered, though the expectation without serum would be only 2 or 3. Other studies show that most cases required up to 120,000 units, though a considerable portion required less than 60,000 units.

Early and Late Treatment: One of the most infortunate current beliefs is that unless serum is given before the 4th day it is useless to employ it. It will be readily seen that most of our cases received serum before the 6th day, but that many bacteriemic cases recovered when serum was given late in the disease, as late, indeed, as the 15th day.

Our bacterienic cases were studied in relation to the day on which serum treatment was instituted, and in relation to the occurrence of, and the number of colonies on the plates (which are taken with 1 c.c. of blood). It is interesting that we did not save patients who had more than 50 colonies if serum treatment was delayed more than five days. Patients with several hundred colonies per c.c. recovered if treatment was undertaken before the 5th day.

It cannot be too emphatically stated that the apparently mild cases treated early require much less serum. Mild cases may become severe and then may require large amounts of serum or be the occasion for a futile attempt to halt what should not have developed—an overwhelming bacteriemia.

In our service at Harlem Hospital,* cases are rated for severity in accordance with a definite scale. Ratings up to 50 are poor, from 50 to 70 fair, and above 70 good. Though most of the non-bacteriemic cases had fair to good rating, it is significant that we saved two cases who were rated as low as 20, and four rated 30. In our first years we saved no cases rated below 40. Better serum and more expert management are now available.

Serum for Other Types: For two of the more recently isolated types we have prepared serums and I am presenting the statistics (Table II). Much depends on the serums. For some of the types we are where we were with Type I and II in 1928. We have serums of insufficient strength and, in some eases, inadequately refined, giving chills and other reactions. We have too few horses on any type to select the best and discard poor producers. The serum except in the case of Type VII, which is amply potent, is usually about 14 the strength of good Type I serum. We can, however, learn from the statistics the chances for success. Though the results are apparently discouraging, the mortality is sufficiently high to spur us to renewed effort. In individual instances, when good serum has been available in ample supply and is not given too late, the results in prompt termination are comparable to the the results obtained in Type I and Type II cases.

Results in Type VII and Type VIII: For Type VII and Type VIII, which constitute together 12 per cent of the cases, the results seem more significant and much more encouraging. In these cases the results are as satisfactory as in Type I. If one takes the non-bacteriemic cases only, the mortality in Type VII is reduced from 12 per cent to 5 per cent, and in Type VIII from 10 per cent to nothing at all. Even in the bacteriemic cases the mortality seems to be reduced. There were 10 cases without serum; 5 died, or 50 per cent. 6 cases received serum; 2 died, or 33 per cent. No one who has studied the cases and has seen the striking results can fail to be encouraged.

For some of the other types there are sera from which in some cases apparently striking results are seen, but the numbers are as yet insufficient to report. Unless funds to continue the production of serums are provided, this work must cease and many lives will be lost. The present status of Type I and Type II serum therapy is due to the great generosity of Mr. Lucius N. Littauer and of the Metropolitan Life Insurance Company. The funds for other types were provided by the same donors and the Altman Foundation. The Lederle Laboratories, Inc., have contributed serums.

I have recommended the early and liberal administration of serum Type I and Type II in all cases as they are the most frequent invaders. But the best treatment of pneumonia requires specific serums of high titre and accurate bacteriologic study. The physician must have this assistance in the treatment of pneumonia if he is not to be handicapped and lose patients he might otherwise save. He will require for his care of respiratory illnesses a set-up which may be as costly as, and an auxiliary technique as specialized as is today given by hospital executives, without question, to surgeons. For their reward they will have results in the saving of lives and in the shortening of

illness as dramatic as are any of the achievements of medicine.

Serum: Refined and Concentrated: The serum used by us is for the most part that refined and concentrated in accordance with the various methods of Felton and of Banzhaf. During 1928, 1929 and 1930, it was prepared by Felton at Harvard. after that by the Lederle Laboratories, Inc., at Pearl River, or in the Laboratory of the Department of Health, New York City, by Banzhaf.

Unfortunately, the serum unit of different manufacturers varies and some of the serums may have only half the strength of others. The units referred to are those of Felton, as originally used, and of Miss Cooper. The later unit proposed by Felton is about half the strength of his original unit

Miss Cooper has frequently verified the approximate correctness of the unitage according to her standards, and where Miss Cooper has obtained a lower value from the one on the original label, this value has been accepted in evaluating the therapeutic effect of the serums.

Parallel tests which Miss Clapp at Pearl River and Miss Cooper at the Research Laboratory have carried out indicate that concordant results may be obtained by employing similar methods and estimating the values by comparison with a common standard serum.

It is desirable that all commercial serum units For this purpose a be of the same strength. standard control serum should be used with all tests. The National Institute of Health has not vet established a minimum standard for refined serum. The present minimum standard permits serums containing only 80 units per c.c. to be marketed. Most of the serums we have employed have contained 2,000 to 3,000 units of Type I. and have been relatively free from chill and other reactions. It is desirable that minimum standards of potency, and standards for maximum frequency of unwelcome reactions in refined and concentrated serum should be promulgated by some competent authority.

Statistical summary is based on experience with individual cases. The presentation of some of these cases lends emphasis to the conclusions that have been drawn.

Case I illustrates the advantage of giving serum without waiting for the type, and also that even massive invasion of the blood stream may be overcome with an adequate dose of serum.

Case Reports: E. S., a man of 35, came in on the 4th day in the serum series receiving serum before waiting for the determination of type. He received 10,000 units of Type I and Type II refined and concentrated serum immediately, and after five hours another dose of 30,000 units. The next day his temperature and pulse were normal. On that day it was determined that his sputum

17

contained Type I organisms and that there had been in the culture from his blood, 454 and 475 colonies per c c on two plates. On the 6th day his temperature rose. On the 7th day an additional 234 000 units were given. Temperature and pulse fell to normal Later there was a moderate serum sickness which lasted for about a week The patient left the hospital perfectly well

Inadequate amounts of serum were Case II uuar athua

A W. a woman of 44, admitted on the 3rd thy on the non serum series, is in contrast with the first case. She was alcoholic. She had had a cold, the onset of pneumonia was with chill and p in in the cliest. The right middle lobe was consolidated and there was pleurisy. She was rated Next day, Pneumococcus Type I was found in mouse' peritoneum and brain, and also in the culture from the patient's lung and in the blood culture On that day there were 2 and 0 colonies on the blood culture plates The next day 38 and 35 colonies were found On this day, 37,000 units of serum were given in small divided doses, preceded by adrenalm because of a history of asthma and a positive ophthalmic test. The following day there was an overwhelming invasion 3 080 and 2 280 colonics on two plates 54 000 units had been given on that day The dosage 91 000 units in two days was entirely inadequate in view of the severity of the infection

Case III illustrates the difficulty in determin ing the type, and the occasional advantage of lung

suction for this purpose

J V, a man of 59, was admitted on the 6th day and received a preparation of Type I and Type II serum which was relatively poor in Type II 2000 and 6000 units of Type II antibody were administered at an interval of 12 hours because the temperature was only in the vicinity of 102° Apparently there was only the slightest effect on the pulse and temperature. On the 9th day, after the crisis it was determined that a lung suction performed on the 7th day contained Type II organisms. There was no growth of pneumococci in the sputiim injected into the mouse

Case IV A case of pneumoma in which Type I invaded blood and pleura with o concomittant infection with Type VIb Recovery ofter administration of Type I sernin, empyeina due to

pneumococcus Type I, and operation
J M, a male of 28, was admitted on the 4th
day as a serum case He received 16,000 units of Type I His blood culture and lung suction were positive The next day 250 000 additional units were administered On the 6th day his temperature was still elevated and his pulse 100 On that day there were agglutinins demonstrable for Type I The following day the temperature

rose and a fresh typing of the sputum was undertaken On the day following, Type VIb formerly known as Type XXVI, was ob tained from the heart of the mouse which had been injected with the sputum. A lung suction undertaken on the 9th day on the same lobe which land originally given Type I revealed Type VIb The temperature continued for two The patient developed agglutinins for Type VIII or XXVI, and finally they were lost Agglutumns for Type I disappeared from the blood reappearing on one occasion and then The temperature continued again disappearing and became more intermittent At this time it became possible to locate an interlobar exudate The pus from this exudate contained Type I On the 30th day of the illness the patient was oper ated upon by Drs Connors and Stenbuck by the Connors packing method On the 5th day his temperature was 100° His wound healed and he remained well

Summary

We are presenting our conclusions based on our experiences in the typing of 1601 cases of pneumonn observed at Harlem Hospital during the last four seasons covering three and three quarter years

We have shown approximately a 50 per cent reduction in mortality in Type I pneumocoecus pneumonias in both bacterienic and non-bacterie mic cases. There is also a shortening of the ill

ness and a saving of sicker patients

The favorable results in Type II are discussed The results of serum treatment for VII and VIII are given. In Types VII and VIII a reduction in mortality of 50 per cent in serum treated over non-serum treated cases is recorded

A plea is made for better serum and a uniform standard of potency the standard to be promul

gated by some competent authority

A plea is made for additional financial support for the experimental production of serum ap preciation is expressed to the donors who made possible the serum treatment of Type I and Type II and contributed to the present studies in other types

It is a privilege to express my deep obligation to Dr. W. linm JJ. Park D rector of Laboratories Department of Health. New York. City who has lirected the pneumonia research to Miss Georgia Cooper who has servegated the types and checked the typ ing and the setum doarse and to Miss Glare Wilear bacteriologist at the Harlem Hospital Station whose careful work executive ability and self secretice is here recorded. I reknowledge my indebtedness to the bacteriological assistants to the successive Pneuriona Service resident physicians and invess and finally to Miss Evelyn Creen and the secretic services of the present of the secretic services of the present of the Death of the Miss Development of Health the Death of the Death of the Miss Development of Teach of the Death of the D

This work wo 11 not lave been possible without the persual interest and encouragement and the generous financial's poort of Mr. Lucius N. Litta ier

THE TREATMENT OF PNEUMONIA BY PHYSIOLOGICAL SUPPORT* By EDWARD E. CORNWALL, M.D., BROOKLYN, N. Y.

HERE is a natural therapeutics which has been evolved during long ages. Living cells, tissues, organs, apparatuses and coordinated organisms possess an inherent capacity not only for normal functioning but also for restoring themselves to normality in greater or less degree when damaged, diseased or deranged. This natural therapeutics is highly developed all along the When a finger is cut the lacerated tissues immediately proceed to restore themselves and to mend the breach in the body wall. When pneumococci penetrate the mucus membrane and invade the human organism the organism immediately puts in operation mechanisms for typing the invading pneumococci, for inventing specific substances which can destroy them or neutralize their activities, and for manufacturing these substances in suitable quantities, besides doing other things which make for the overcoming of the disease. The operation of these natural therapeutic procedures requires a certain amount of time; natural therapeutics is apt to be slow; but it is always exercised in the right direction and is correct as far as it goes. It is truly regular medicine.

There is another therapeutics which human intelligence has developed. This is the therapeutics of the physician. Its development is already well advanced and promises much greater advance-

ment in the future.

The physician can apply his therapeutics in two ways: He can help nature in her curative operations, and he can seek his therapeutic objective by direct means, and even by means which disturb or contravene regular physiological processes. He can treat his patients by physiological support and he can treat them specifically.

Specific treatment promises more than physiologically supportive treatment; it may even promise to cut short the disease or to insure a cure; but it is not universally available. Physiologically supportive treatment has the constant

merit of being universally available.

In contributing to the present discussion of the treatment of pneumonia I shall confine my remarks to the treatment by physiological support. How can we help the patient to cure himself?

The general answer is, by making conditions favorable for the operation of his own intrinsic method of treatment, which we know can be successful in a large proportion of the cases.

We can favor the patient's physical rest by putting him in bed and allowing him to make only such movements as are good for him or are not detrimental, and by avoiding unnecessary and disturbing physical examinations. We can favor his mental rest by an encouraging manner and en-

couraging words, and by restricting conversation, visiting and noise. We can regulate ventilation so that he gets fresh air and is at the same time protected from chilling. We can regulate his diet in accordance with the indications presented by his pathological physiology. We can safeguard him against dangers which threaten from the alimentary tract, particularly gaseous distention, toxemias and reflex vasomotor disturbances, both by regulation of diet and by wise management of the bowels. We can see to it that he has good nursing, and also, that he is safeguarded against meddlesome nursing, such, for example, as the giving of full sponge baths when he is very sick. And we can resist the influence of wrong therapeutic traditions and teachings and our own misguided zeal which would lead us into meddlesome medi-

How can we put into practice these general directions for physiologically supportive treatment?

There are no standard, universally accepted procedures for the treatment of pneumonia outside of rest in bed and general nursing. Even in regard to hygienic and dietetic treatment there are differences of opinion; and extensive differences of opinion exist in regard to the treatment of symptoms.

My opinions on the treatment of pneumonia and the details of the treatment which I prefer may be found in the thirty-one papers on the subject which I have published during the last twenty-two years. I cannot in this short paper repeat those details, but I will discuss briefly a few points

in that treatment.

Fresh air. Fresh air should be provided. But the mistake of confusing cold drafts with ventilation should be avoided. The patient should be protected from chilling. The widely used quasi specific treatment known as the cold air treatment, which seems to have for its basis a distortion of the indication for fresh air, I look on as dangerous. It is capable of doing harm, especially when the temperature is low, and the time of defervescence is near. Writing in 1913 I called attention to the fact that such treatment continued after defervescence, when the patient lies weak and perhaps perspiring, may induce reinfection of the lungs or an attack of pleurisy.

The bowels. Twenty years ago I came to the conclusion that the traditional practice of beginning treatment regularly with an artificial clearing out of the bowels and continuing treatment with routinely induced daily bowel evacuations, was not good medicine in pneumonia. I was pleased to find support for this opposition to a well nigh universal practice in Hippocrates' Second Aphorism, which says: "Artificial evacuations of the bowels, if they consist of such matters as should be evacuated, do good and are well

Read before the Medical Association of the Greater City of New York, held at the Academy of Medicine, New York, November 21, 1932.

borne, but if not, the contrary." Reasons for this conservative management of the bowels suggest themselves as follows: Artificially induced movements of the bowels disturb the patient more than They favor inthose which occur naturally. creased fluidity of the bowel contents, and increased bacterial growth therein and absorption of toxins therefrom. They predispose to gascous They excite nervous reflexes which can seriously disturb the heart and vasomotor system, especially when the blood pressure is low, which is often the case in pnuemonia. They can even put a patient with an unstable cardiovascular system in jeopardy from the physical exertion and nervous reflexes involved. And in the case of some cathartic agents they can cause introduction into the blood stream of injurious substances.

This conservative management of the bowels does not mean that they should never be moved artificially in pneumonia; but that they should be moved only when special indications for moving them exist other than failure of regular daily evacuations. Such special indications may be tympanites which regulation of diet does not correct, or a disagreable sensation of fullness in the rectum. Also, if the patient is first seen early in the disease, and has not had a movement within twenty-four hours, and is in good condition, an enema may be given. And sometimes in the middle of the course of the disease, if no evacuations have taken place naturally, and the patient is in good condition, an enema may be given. regularly on the second day after defervescence, if natural evacuations have not taken place, an enema should be given. Enemas should be cmployed to move the bowels and not cathartics given by mouth. It is the general rule that the bowels should not be moved artificially in the presence of notable circulatory or respiratory embarrassment or near the expected time of deferves-Evacuations often take place naturally, and these do not much disturb the patient. This conservative management of the bowels requires special regulation of the diet, and also avoidance of disturbing medication, and not only disturbing cathartic medication but also other disturbing medication.

I have had twenty years experience with this policy of conservative bowel management in pneumonia and am convinced by clinical evidence that

it makes for physiological support.

Dict. The subject of diet has not received generally the attention which it deserves. Proper regulation of the diet means much for physiological support in pneumonia. Definite dietetic indications are presented by this disease and its complications. Being a disease of short duration, it is possible to take advantage of moderate undernutrition: the protein and fuel rations can be moderately diminished with consequent relief to the overworked bodily metabolism. A large water ration is indicated to facilitate metabolism and

elimination; but, on the other hand, circulatory weakness or renal insufficiency may require that the water ration be restricted. Fever calls for increased rations of alkaline salts to offset the acidic tendency of fever; and the leucocytosis and fibrinous exudation into the lungs and increased metabolism call for an extra ration of calcium. The dangers which threaten from the alimentary tract, particularly to the cardiovascular system, call for a diet which will safeguard against toxemias of intestinal origin, visceral distention and reflex nervous disturbances.

The dietetic indications in pneumonia vary with the severity of the disease and with complications. For the average case which is doing well I am accustomed to prescribe a fluid, lactovegetarian diet which supplies about forty grams of protein, two grams each of sodium chloride, sodium bicarbonate and calcium chloride in addition to those salts present in the other articles of food given, and about 270 grams, or 90 ounces, of water. The proper fuel value of the food is about 1,200 calories. The articles which enter into this diet are water, barley water, modified milk, strained fresh orange or grapefruit juice, lactose and dextrose, and the salts above mentioned.

This may be considered a full diet for the fabrile stage. It has to be modified to meet conditions and complications. In severe cases it may be necessary to reduce the quantity of milk or water. In very severe cases it may be necessary to restrict the diet temporarily to strained orange juice, dextrose or lactose, barley water, water, and the salts mentioned. The presence of tympanites calls for exclusion of milk, or the giving of it in limited quantity lactacidized. The presence of diarrhea calls for a diet mostly of barley water and salts. Notable heart weakness calls for reduction of the fluids, and, perhaps, increase of the sugar; but it is not often that the reduction of the fluid need be extreme. It is usually good practice in the more severe cases, and near the expected time of defervescence, to reduce the milk and water in the diet.

Among the articles of food often given in pneumonia which I consider objectionable, may be mentioned raw egg albumin, animal broths, and the patent foods which feature the words "peptone" and "peptonoid."

Cardiac and circulatory failure. Here urgent need for physiological support often appears. This support ean be given indirectly by rest, conservative bowel management, and regulation of the diet. It can also be given directly by administration of drugs which increase the functional performance of the heart and blood vessels.

In discussing this phase of pneumonia therapeutics one can hardly avoid some reference to the use of digitalis, because of the dominating influence which that drug exercises on medical practice. I will only say in this connection, that during the last twenty years, as near as I can

recollect, I have not prescribed digitalis in the active stage of pneumonia excepting on one occasion; holding the opinion that this drug is undesirable in pneumonia, and particularly on account of its effect on the vagus mechanism.

The drug which as a result of experience I have come to prefer above all others for use in the treatment of circulatory failure in pneumonia is strophanthin. Caffeine and strychnine I also use occasionally as adjuncts. In speaking of the use of these drugs I wish to emphasize the importance of being careful not to give them in too large doses. The judicious use of the foods, sugar, and calcium, also have an important place in the treatment of circulatory failure. After administration of caffeine and strychnine the patient should be watched for unfavorable effects; for these drugs even in small doses are occasionally not well borne. Very rarely an idiosyncrasy is observed in regard to strophanthin.

Opiates. Sleep artificially induced early in the disease may be of great value for physiological support. Pleuritic pain, distressing cough, and great restlessness which prevent sleep may properly be relieved by opiates in the early stages of the disease. Later in the course of the disease, however, and especially near the expected time of defervescence, opiates are contraindicated; for then it may be necessary for the patient to keep awake and to breathe rapidly in order to survive. The opiates should always be given in comparatively small doses. Sedative drugs other than opiates should generally be avoided, excepting

possibly alcohol in selected cases; but not every patient takes alcohol well. In the treatment of delirium physical restraint, in my opinion, is generally to be preferred to the use of opiates or other sedative drugs.

Dyspnea. Nature makes physiological adjustments for dyspnea in pneumonia by increasing the respiration rate. In severe cases stimulation of the heart by strophanthin and of the respiration by caffeine is called for. In very severe cases, with extensive pulmonary involvement, the conservative use of oxygen by inhalation may be indicated.

In concluding these few remarks on the treatment of pneumonia by physiological support I wish to emphasize the importance of self restraint in our therapeutic activities. After we have put the patient in the position and conditions favorable for the operation of his own intrinsic method of treatment, we should go about the giving of directly supporting or symptomatic treatment with caution and care. In giving such treatment our ideal should be, the least that the patient can get along with rather than the most that he can stand. A patient with pneumonia will get well if only he can be kept alive long enough. Unfortunately we can not always keep him alive long enough. But physiologically supportive treatment which is possible in the present state of knowledge can be relied on to reduce considerably the current mortality rate.

WHY A CHILD REFUSES TO EAT*

By DOUGLAS P. ARNOLD, M.D., BUFFALO, N. Y.

The subject of refusal of food is one of the most common and one of the most exasperating of all pediatric problems. It is a subject which has been approached by many different men; their ideas on the etiology and therapy are legion and seem to be limited only by the number of authors. In looking over the literature, we find that all agree that no child can be expected to be blessed with a good appetite while harboring an infection, be it syphilitic or chronic respiratory, or urinary; and so this phase will be eliminated from this short paper.

Many children have been adenectomized, tonsilectomized, yes, even circumcised, and there still remains a large army of well trimmed and untrimmed food fighters among the young children, and conscientious passive objectors—among the older ones. Why is this?

The literature on anorexia is a maze of endo-

*Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

crines; vitamines; liniar types; gastric balloons; stomach waves; distended colons; abdominal pads; metabolic rates; hydrogen-ion concentrations; bland low-residue diets; stimulating diets; raw basic feedings without meat; the preponderance of basic over acid-forming elements; and the opposite; emphasizing the giving of liver, beef and kidneys; the exclusion of milk altogether, replacing it with fruit juice, and the giving of a quart of milk a day. (All, I believe, concur in the dangers of too much milk.) Some authors mix cause and effect, for the reason that they start the study too late and after the condition has brought about marked secondary changes.

I do not wish to give the impression that I am over critical; many good points have been evolved, truths are found in most of the studies but I still contend "They do not see the woods for the trees"

trees."

No one having a pediatric practice can but realize that in our little patient we are dealing with a

^{1.} For a bibliography of previous papers by the author on the subject of pneumonia, see the Medical Times and Long Island Medical Journal of February, 1932.

personality,—usually a very dominating personality mixed with a strong element of negativism. If this were not so, we would wend our way home at nightfall much less tired and much more anniable.

From the foregoing, it must be evident that the theme of my paper is that we are dealing primarily with a psychological problem with resulting physical effects on the body economy. Do not misunderstand me, this is not a problem for the psychiatrist or behaviorist, but is distinctly a pediatric problem. In this connection I cannot refrain from advising you to read that enchanting sane article from the fluent pen of Joseph Brennennann, "The Menace of Psychiatry," American Journal of Diseases of Children, August, 1931.

The subject resolves itself into proplylaxis, and the treatment of the established case. I will confine myself today to a short discussion of the

more important phase-prophylaxis.

Of prime importance, conflict over food must be avoided from the date of birth. There is too much competition in weight-gaining during infancy and childhood, and this one fact gives the child the whip landle throughout its young life. It does not take a child long to sense that fat babies and thin mammas are the style. The fattest baby is not necessarily the best baby. Many babies are started on their food-fighting career the first weeks of their lives by overzealous complementing, supplementing, and foreing.

It may take much finesse to establish the proper attitude toward food intake. Necessary factors are good lygiene and all that term applies; in the breast fed, correct posture at the breast; in the artificially fed, attention to nipples and the temperature of the food. Give as infrequent feedings as is consistent with getting-in the twenty-four hour amount, remembering that this is a variable quantity. Allow the child possibly to feel a little hungry rather than stuffed like the "Strassburg Goose," at the end of a meal.

Children are creatures of habit, and the older they are, the more opinionated they become. This is the reason for instituting an early bottle in a breast fed infant, and for the early giving of cod liver oil, orange juice, and solids. The children should be "eased-in" to every change, and not pounced upon. They must be given time to accustom themselves to different tastes, different methods of giving, and other changes. A child must be enticed, not coaxed or forced. Meal time should be a happy quiet time. A mad cabaret with one or more of the family acting as whirling dervishes has no place at the child's meal time. Quiet conversation, interesting to the child, is

often of advantage. A nurse or mother should be educated along these lines, and made to realize the importance of these feeding details, for unless they show some intelligence in coping with the common first refusal, great harm is done and the endless fight is on.

There is much to commend the work of Dr. Clara Davis in the self selection of diet, that is, making certain that wool, plaster, and particularly paint are not among the dietary, for a child does not always eat or need what is seems to crave—nothers and grandmothers to the contrary.

Lastly, never force !- A child, like an adult, will have meals, yes, days, in which it is not hungry. One ill-advised forcing can be the inception of a food fighter or objector, or may teach the child that other weapon of defense-vomiting. This often comes about at the time of an illness, when the anxiety to present starvation acidosis, hypoglycemia, and loss of weight causes mother, nurse and doctor to err and at this time form in the child an obsession, association reflex, conditioned reflex, or call it what you will, against food. The child soon sees that it has a powerful weapon over its subjects and comes to have an exaggerated idea of its importance in the community, if not in the family. "He wields his sceptie with a despot's hand, baby, my king."

I firmly believe that if doctors, mothers and nurses were taught the importance of anorexia prophylaxis, behavior problems in feeding would be a thing of the past.

A paper on this subject should not be written without an appreciation of Dr Charles Anderson Aldrich and his little book "Cultivating the Child's Appetite."

THE MINORITY REPORTS OF THE COMMITTEE ON THE COSTS OF MEDICAL CARE

By NATHAN B. VAN ETTEN, M.D., NEW YORK

Delivered at the National Conference of the Costs of Medical Care, New York Academy of Medicine, November 29, 1932.

I have the honor, Mr. Chairman, to comment briefly upon some divergent visions of a few members of our Committee upon the solution of the problems of "The delivery of adequate scientific medical service to all of the people, rich and poor, at a cost which can be reasonably met by them in their respective stations in life." All of the studies were pointed at this target or at sources of reflected light which might illuminate it.

The work of the Committee carried on by exceptionally able directors and staffs, is monumental and we learned much about adequacy costs, and distribution, and the details of many experiments supported by masses of statistics which were delivered so rapidly and so continuously that there was some inevitable indigestion when we suddenly changed into gentlemen of the jury who must weigh evidence and recommend cures for a faulty

social operation.

All concurred in praise of the diligence, skill and logical presentment of the findings and in most of the interpretations. All tried to harmonize themselves into unanimity with such success that upon only a few fundamentals or implications are there dissentient opinions. One believes that the report has missed the target; another that the recommendations have fallen short; and others believe that the mark has been overshot by excursions into Utopian idealism.

The objections of the minority composed of eight physicians and a clergyman, are to the recommendations in "Organization of Medical Services" and "Group Payment for Medical Services." The minority report of two leaders in the national dental organization is in general accord with the first minority, but in agreement with the majority upon "Group Payment."

The minorities desire changes in medical education, urging-in addition to the present scheme which seems to qualify sufficiently for the care of 80 per cent of the ills of mankind-emphasis upon the development of clinicians and added accent upon the importance of teaching disease They wish that mere prudential ethics may be strengthened by spiritual ethics and that only those possessing high character and high educational qualifications be admitted to the professions.

Premature specialization and overspecialization will be cured by the special societies acting within themselves, and the evolution of dentistry into whatever its destiny as a department of medicine will be determined by the concerted action of a well organized profession.

The minorities object to contract practice when-

ever it operates in restraint of opportunity for all competent and reputable physicians in the community, or results in unfair competition or furnishes inferior medical services. The same objections are made to pay clinics when operated for profit by laymen as "exploitation of the public and of the medical profession" through inferior quality of service with no lessching of the costs of medical care to the patient who must add operative charges to the normal or average fee prevailing in the community.

The minority claims overemphasis upon the virtue of group clinics and cites in opposition the large number of groups treating patients under workmen's compensation laws, in active competition one with another, "soliciting patients through paid agents." Many of these groups are under lay control-keeping down costs by employing physicians of low ability, commercializing medical practice, lowering ethical standards, demoralizing physicians into undignified advertising in factories reminiscent of the old lavatory pasters, leading physicians to compete for practice by buying cases for one-third or one-half of their fees and, in collusion with agents, prolonging treatments far beyond reasonable limits and padding their bills, as developed publicly by the Seabury investigation this year, and not denied.

The minority objects to the influence of this Committee being used in the promotion of new forms of political bureaucracy, feeling that the unsatisfactory operation of the forms of compulsory sickness insurance now carried on in fortyfour states under workmen's compensation laws has degenerated into racketeering in our large cities and should be corrected by legislative action which should lead to real revision of these operations and carry them into the administrative hands of those who represent the higher medical honor and higher medical intelligence of the community.

Here the hospital or medical center may furnish the place and the skilled staff service, all of which should be amply paid for.

No arguments demonstrate a quality of service, in countries where compulsory health insurance prevails, which is superior to the admittedly inadequate and badly distributed service now operating in the United States. Quoting from Simons and Sinai: "Contrary to all predictions, the most startling fact about the vital statistics of insurance countries is the steady and fairly rapid rate of increase in the number of days the average person is sick annually and the continuously increasing duration of such sickness. Various studies in the United States seem to show that the average recorded sickness per individual is from

seven to nine days per year. It is nearly twice that amount among the insured population of Great Britain and Germany, and has practically doubled in both countries since the installation of insurance."

The minority report states:

"It ought to be remembered that compulsory insurance will necessarily be subject to political control and that such control will inevitably destroy professional morale and ideals in medicine. Since a qualified and untrammelled medical profession is the only agency through which scientific medicine can be applied for the benefit of the people, it follows that any plan which destroys professional morale will bring disaster to the public."

Quoting again from Simons and Sinai:

"While the statement might be disputed by insurance societies, a comparative study of many insurance systems seems to justify the conclusion that the evils of insurance decrease in proportion to the degree that responsibilities, with accompanying powers and duties, are intrusted to the medical professions."

This statement is both a challenge to the medical profession and a warning to those who, without proper consideration of that profession are willing to recommend the adoption of various new

plans for the care of the sick.

The minority feels that our Government has strained paternalism far beyond moral justification in the extension of veterans' hospitals and in the hospitalization of veterans with non-service disability and has spent the people's money with inexeusable recklessness. This sorry exhibition should make us all shy of Gevernment invasion into control of any phase of medical practice, except, of course, in the field of public health and in the institutional care of those unemployable wards of the State—the tuberculous, the insane, the feeble-minded, or the hopelessly crippled.

The minority objects to the large medical cen-

ter as projected by the majority on the ground of exclusion of many physicians, of oppressive competition, of big business technique erecting machinery which eliminates personality and destroys personal relations by factory forms. Mere bigness is often a liability. The city of New York is so big that real community interest and civic pride are crushed and the citizen taxpayers are too numb to protest against a self-perpetuating political machine which rides them.

The minority recognizes the practicability of centering medical service in small places where there are only one or two hospitals and where all of the physicians of the community are permitted to use all of the facilities of the hospitals in a true community spirit, the institution being supported by taxation or by gifts. My personal opinion is that if all hospitals were open to all reputable physicians (not merely the laboratory facilities but beds as well) many of the problems of public service would be solved. I had always believed this to be administratively impossible until it was positively demonstrated to run smoothly in a very large hospital. Places where there are no hospitals and few physicians, dentists or nurses, must be served in other ways with the entire health service of the country concentrated upon ways of distributing urban surpluses into neglected fields.

The minority favors continued study of group practice: co-ordination of the medical, dental, pharmacentical, lospital, and nursing professions; the study of the application of the insurance principle to the accumulation of reserves, and to the assurance of solvency of institutions.

The "challenge of the future" in the majority report is a vigorous, stimulating statement that the work is not only not finished but only just begun, and that continuous widespread efforts must be carried on through all medical, educational, and all other agencies whose interest leads them earnestly to desire the prevention of disease and the general health of our people.

Annual Meeting, April 3-5, in the Waldorf-Astoria, New York City.

MEDICAL SOCIETY ACTIVITIES

The physicians of New York State, both individually and also collectively in their medical societies, are redoubling their efforts to make all forms of medical service available to all classes of people. This issue of the Journal, the first in the new year, contains an assortment of reports of activities of unusual interest. There is an editorial on the report of the Committee on the

Costs of Medical Care on page 25; and on page 22 there is an exposition of the attitude of practising physicians toward the majority report of the committee. Then there are the reports on page 34 showing how large groups of physicians are already far advanced in finding medical solutions to problems for which insurance schemes are offered as a universal remedy.

THE QUALITY OF MEDICAL CARE

The final report of the Committee on the Costs of Medical Care might well have rested upon a résumé of the studies in which are assembled masses of data which will be invaluable to students of public and private medical service in future efforts to advance the health status of the people of the United States.

The factual accumulation is ample justification for the existence of the committee. The medical profession-the efficiency engineers-the social experts and the facultics will each interpret the findings differently and will be inspired to attempt experiments which will carry the colors of

their traditional thinking.

Socialized medicine, mass medicine, contract medicine, commercialized medicine and governmental medicine are vividly painted in the majority report as solutions for difficulties of medical care to all of us who have annual incoincs below twelve hundred dollars.

Idealistic programs are indicated which seem to promise quantity of service rather than quality of service; and while also claiming to protect the personal relationships between physician and patient, carry no conviction to the practising physician whose practical experience with our present large hospital groups tells him that new privileges are not for him.

It is natural that there is no promise to lessen the national health bill, and there cannot be if adequate service is delivered based upon our present knowledge of the eost of delivering it.

The bill promises to be larger without improving the income position of the physician. The arguments for voluntary insurance schemes, immediately followed by elaborate statements that all voluntary insurance is futile and invariably leads to required insurance after the European manner, is disheartening to those whose experience with provident insurance leads them to think that insurance budgeting for future catastrophe or the decadence of age promises security and is capable of extensive application.

The proposal of per capita contract schemes for serving large groups of individuals under the aegis of all sorts of direction, with no guaranty of the quality of medical care or the character of personnel, also seems to lead to inferior service to the sick and to inevitable governmental control.

Proposals for better community service originating in and earried on by county medical societies receive scant attention in the majority report, the authors of which seem to be satisfied that their opinion is of a superior fabric to that which binds together the one hundred thousand members of the American Medical Association who live with these problems and are daily trying to improve

the quality of medical care.

After the first chapter, the majority report staggers through one hundred and seven pages of idealistic and materialistic suggestions of programs with frequent genuflection and finally prostrate obeisance to compulsory health insurance. In the last chapter some clearer headed writer almost entirely divests himself of nebulae and issues a "challenge of the future" which is a splendid call to the best that is in our medical ambition.

The minority report seems to be based on the practical experience of its authors who cannot be diverted from the realities of their investment in the practice of humanity into speculative fields which might imperil the quality of their service. The minority is neither satisfied with things as they are, nor smugly complacent in thinking that things cannot be improved. They see the evolution of medical service as a slow process, but believe that it will meet changing social currents warmly and sympathetically.

The minority believes that experiments with new forms of service should originate in the county medical units and be tried there; and that all physicians should be enlisted under one ideal which should be the delivery of the best service of scientific medicine possible, in all its forms, to all of the people.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Ideals of Peace:-This Journal of January, 1908, contains the following editorial on the appeal of Jane Addams for the abolition of war:-

"She says that we are even now discovering moral substitutes for the war virtues in the struggle toward a higher social order. The newer heroism manifests itself at the present moment in a universal determination to abolish poverty and disease, a manifestation so widespread that it may justly be called international.

"In illustration of this new determination, it is shown that one immediately thinks of the inter-

national effort to rid the face of the earth of tuberculosis, in which Germany, America, Italy, France and England are engaged with such en-This movement has its international thusiasm. congresses, its discoverers and veterans, also its decorations and rewards for bravery. cipline is severe; it requires self-control, endurance, self-sacrifice and constant watchfulness. Its leaders devote much time to careful study and demonstration, they reclaim acres of bad houses, and make over the food and water supplies of large cities.'

Then there are the reports on page 34 showing how large groups of physicians are already far advanced in finding medical solutions to problems for which insurance schemes are offered as a universal remedy.

Resection of the Superior Hypogastrie Plexus to Overcome Functional Disturbances in the Female Pelvis .- A report is made by Ure Max Meier of his results in 8 cases in which he carried out Cotte's operation for dysmenorrhea and pelvic neuralgia. The procedure is very simple in its technique, and involves as little danger as any laparotomy can. The abdomen is opened, the intestine pushed aside, the posterior leaf of the peritoneum incised over the 5th lumbar vertebra, and the entire structure of nerves, cellular tissue and lamellae between the two common iliae arteries bluntly mobilized, and removed over a length of 11/2 to 3 cm. Care is taken to avoid injuring the left iliac vein, which passes under this level, and also the superior hemorrhoidal artery and vein, if the mesosigmoid is inserted very close to the median line. No macroscopic lesion was found in any ease, and for this reason the reseetion of the superior hypogastric plexus was alone performed. All the patients were married women with several or many children, and most were between the ages of 30 and 36. The immediate postoperative course was normal, with the exception of one case in which a thrombophlebitis appeared. As regards end-results, one case of pure dysmenorrhea and 2 of pelvic neuralgia were completely cured; a 4th case was locally cured but showed little general improvement owing to a psychoneurosis; 2 eases were greatly improved, and I slightly so; while I showed no improvement whatever. Histologic examination in 9 cases (5 of this group, and 4 more recent ones) showed everywhere fresh bleeding and local edema, and perineural sclerosis of greater or less degree, which bore no strict relation to either the data of the history or to the result of the operation. In I case there was a striking increase of intraneural connective tissue with sclerosis, by which the nerve bundles had become split up. Inflammatory cell infiltrates were found in 2 cases, one of these being the case in which no improvement was accomplished. It is Meier's belief that cases with inflammation present should first be treated with diathermy, and Cotte's operation used only as a last resort. He regards the procedure as indicated definitely in pure essential uterine dysmenorrhea, with no pains in the intermenstruum; but he thinks it should be used only with great caution in the group of chronic or paroxysmal cases without gross anatomic defect, in which psychic conditions may play a large part. - Schweizerische wedizinische Wochenschrift, October 22, 1932.

Treatment of Infantile Paralysis.—A review is made by H. Finck of 140 cases of infantile paralysis which he has treated by irritation therapy since 1924, including the severe epidemic of that year. His success was brilliant: no paralysis appeared in any of the cases which reccived an injection early in the course of the symptoms. The temperature, high in most

cases, fell after 24 hours and the severity of the symptoms abated. It made no difference whether the treatment was omnadin, aolan, vatren-easein or simply sterilized milk: the important thing apparently was that the injection be performed early. In cases in which the treatment was not given until a little later period of the disease, the good results were less prompt or were entirely wanting. In such cases injections had to be made repeatedly, and it was 2 or 3 days before the temperature dropped, and then only gradually, of the 18 children injected on the second day did any paralysis occur, and only one of these children received more than one injection. Of the 4 injected on the third day, 3 were cured, and I remained slightly paralyzed. these 4 received more than one injection. Of 3 treated on the fourth day, only I was cured. One child injected first on the seventh day is now a eripple in both legs. In this case the parents refused to allow further treatment after 2 injections, regarding it as useless. However, a comparison with untreated cases gives the impression that even in cases not treated until late the poor results were reduced to a minimum if the injections were continued. Prophylactic injections had no effect whatever. The fact that in a number of cases there were recurrences while brothers and sisters in the same family again escaped infection suggests a certain predisposition. To the possible objection that if treatment must be given so early to prevent paralysis, there is no sure proof that the cases were really infantile paralysis and not plain uncomplicated grip, Finck replies that in the great majority of cases cerebral symptoms were present, and that, even without these, the diagnosis was justified by the severe clinical picture, with high fever and sudden onset, generally without any definite symptoms beyond headache or sensitivity of the upper dorsal vertebrae, and by the absence of any other epidemic and the paralysis appearing in many other children at the same time and place, and with the same symptomatology. -Münchener medizinische Wochenschrift. November 11, 1932.

A New Method of Blood Examination for Diagnosis of Cancer.—Despite the many fruitless methods of examination, it may be assumed, says Hans J. Fuchs, writing in the Münchener medizinische Wochenschrift of October 21, 1932, that cancer is accompanied by considerable changes in the nature of the blood. Serologic methods have been confronted by the difficulty that in the preparation of antigens one can hardly ever be absolutely sure that portions of normal tissue have not also been present in the extract. Fuchs' own method, the "Ca R" (cancer reaction), first

MEDICAL PROGRESS

Auriculoventricular Dissociation Course of Acute Articular Rheumatism.cording to A. Clerc, S. Vialard, and Balaceanu, it has been possible to find in the literature some 50 cases of acute articular rheumatism in which dissociation was auriculoventricular These authors have noted it in 3 per cent of their own 63 cases. As a rule, the dissociation appears after the fever and the arthropathy have reached their maximum, and accordingly in cases that are relatively severe, though cases have been observed in which the alteration of rhythm preceded by days or even weeks the appearance of articular symptoms. Once established, the dissociation is rather frequently incomplete, either in that the block of auricular contraction occurs regularly (at every second beat, for example) or that it appears at variable intervals, resulting in a certain irregularity in the ventricular contractions and in the radial pulse which reflects them. Complete dissociation has, however, been recorded by a number of writers, and was observed in 2 of the authors' 3 cases. The classic expression of the affection as bradycardia has not always been present. The frequent instability of the anomalous rhythm is a striking feature. In the majority of cases the anomaly is transitory, disappearing after a few hours, not to return, or alternating with normal periods or with other abnormal rhythms that may coexist with it. Except in rare cases with sudden fatal termination, the dissociation tends toward spontaneous cure, after days, weeks, or occasionally, months. Diagnosis is made by the electrocardiogram, which not only reveals anomalies that give neither subjective nor circulatory signs, but also makes it possible to follow the course day by day. Prolongation of the P-R space need give no uneasiness as the possible prelude to a physiopathologic transformation, for in the great majority of cases it is transitory. Only 5 cases are found in the literature in which a syncopal attack was followed by death. With reference to the mechanism of production of this dissociation, it seems probable that the fibers of the bundle of His must be implicated. In the few cases in which such hearts have been examined microscopically, specific Aschoff bodies have been found present in the His bundle. salicylates being contraindicated, they remain the treatment of choice, and should be administered intensively. Further study is desirable, over a long period in order to prove whether or not a permanent future dissociation is liable to appear. Bulletin de l'Académie de Médeci ne, October 25. 1932.

When Should Operation Be Done in Acute Primary Pneumococcus Peritonitis? - This question, says A. Ciminata, writing in the Riforma medica of September 24, 1932, constitutes the focal point in the entire chapter of acute diffuse peritonitis. The difference of opinion with reference to intervention in this type of peritonitis is concerned not with any debate as to the necessity of operation, but only as to the stage at which it should be carried out. This question is inseparable from the element of diagnosis, the difficulty of which constitutes the major obstacle confronting the surgeon. Three stages are recognizable in pneumococcus peritonitis. In the first there is no pus, but an intense congestion of the ileum and cecum, in which the appendix participates, although it shows no changes of a special nature. Cultures made at this time from the peritoneal cavity may not reveal the presence of the pneumococcus, supporting the hypothesis of a toxic congestion caused by inflammation of the ilcocecal tract without the pneumococcus having yet reached the peritoneal cavity. Blood cultures, if positive (and they are often negative) are likely to be so only in the initial stage. In the second stage a purulent exudate has already formed, which is diffused throughout the abdominal cavity, the intestinal loops literally wallowing in pus. In the third stage the intestinal mass is covered with a fibrinous film and large collections of pus lie between this and the abdominal wall. The pus has a special character, being creamy, yellow and odorless, in addition to its fibrinous content, whereas that of appendicitis is fetid, contains no fibrinous masses and is of a rather dark color. Ciminata outlines 8 cases, the first 2 of which were operated on in the first stage, the next 2 in the intermediate stage, and the other 4 in the third All the first 4 died after operation, no amelioration in the peritoneal symptoms having been noted. On the contrary, all the last 4 patients, in whom the pus had formed collections and was confined by formation of fibrinous films. which appeared to be a defense on the part of the peritoneum, wrapping up the mass of intestines like a bundle, promptly improved after operation, and terminated in complete recovery. From this we may conclude that operation is not indicated in the first or second stage, but that the results of surgical intervention in the third stage are highly gratifying. This conviction is in accord with the opinion of the majority of authors, who hold that early operation precipitates the worst ills of the disease, making the course of the affection more grave.

Resection of the Superior Hypogastric Plexus to Overcome Functional Disturbances in the Female Pelvis .-- A report is made by Ure Max Meier of his results in 8 cases in which he carried out Cotte's operation for dysmenorrhea and pelvic neuralgia. The procedure is very simple in its technique, and involves as little danger as any laparotomy can. The abdomen is opened, the intestine pushed aside, the posterior leaf of the peritoneum incised over the 5th humbar vertebra, and the entire structure of nerves, cellular tissue and lamellae between the two common iliac arteries bluntly mobilized, and removed over a length of 11/2 to 3 cm. Care is taken to avoid injuring the left iliac vein, which passes under this level, and also the superior hemorrhoidal artery and vein, if the mesosigmoid is inserted very close to the median line. No macroscopic lesion was found in any case, and for this reason the resection of the superior hypogastric plexus was alone performed. All the patients were married women with several or many children, and most were between the ages of 30 and 36. The immediate postoperative course was normal, with the exception of one case in which a thrombophlebitis appeared. As regards end-results, one case of pure dysmenorrhea and 2 of pelvic neuralgia were completely cured; a 4th case was locally cured but showed little general improvement owing to a psychoneurosis; 2 cases were greatly improved, and I slightly so; while I showed no improvement whatever. Histologic examination in 9 cases (5 of this group, and 4 more recent ones) showed everywhere fresh bleeding and local edema, and perineural sclerosis of greater or less degree, which bore no strict relation to either the data of the history or to the result of the operation. In 1 case there was a striking increase of intraneural connective tissue with sclerosis, by which the nerve bundles had become split up. Inflammatory cell infiltrates were found in 2 cases, one of these being the case in which no improvement was accomplished. It is Meier's belief that cases with inflammation present should first be treated with diathermy, and Cotte's operation used only as a last resort. He regards the procedure as indicated definitely in pure essential uterine dysmenorrhea, with no pains in the intermenstruum; but he thinks it should be used only with great caution in the group of chronic or paroxysmal cases without gross anatomic defect, in which psychic conditions may play a large part .- Schweizerische medizinische Wochenschrift, October 22, 1932.

Treatment of Infantile Paralysis.—A review is made by H. Finck of 140 cases of infantile paralysis which he has treated by irritation therapy since 1924, including the severe epidemic of that year. His success was brilliant: no paralysis appeared in any of the cases which received an injection early in the course of the symptoms. The temperature, high in most

cases, fell after 24 hours and the severity of the symptoms abated. It made no difference whether the treatment was omnadin, aolan, vatren-easein or simply sterilized milk: the important thing apparently was that the injection be performed early. In cases in which the treatment was not given until a little later period of the disease, the good results were iess prompt or were entirely wanting. In such cases injections had to be made repeatedly, and it was 2 or 3 days before the temperature dropped, and then only gradually. of the 18 children injected on the second day did any paralysis occur, and only one of these children received more than one injection. the 4 injected on the third day, 3 were cured, and I remained slightly paralyzed. these 4 received more than one injection. Of 3 treated on the fourth day, only I was cured. One child injected first on the seventh day is now a cripple in both legs. In this case the parents refused to allow further treatment after 2 injections, regarding it as uscless. However, a comparison with untreated cases gives the impression that even in cases not treated until late the poor results were reduced to a minimum if the injections were continued. Prophylactic injections had no effect whatever. The fact that in a number of cases there were recurrences while brothers and sisters in the same family again escaped infection suggests a eertain predisposition. To the possible objection that if treatment must be given so early to prevent paralysis, there is no sure proof that the eases were really infantile paralysis and not plain uncomplicated grip, Finck replies that in the great majority of cases cerebral symptoms were present, and that, even without these, the diagnosis was justified by the severe clinical picture, with high fever and sudden onset, generally without any definite symptoms beyond headache or sensitivity of the upper dorsal vertebrae, and by the absence of any other epidemic and the paralysis appearing in many other children at the same time and place, and with the same symptomatology. -Münchener medizinische Wochenschrift. November 11, 1932.

A New Method of Blood Examination for Diagnosis of Cancer.—Despite the many fruit-less methods of examination, it may be assumed, says Hans J. Fuchs, writing in the Münchener medizinische Wochenschrift of October 21, 1932, that cancer is accompanied by considerable changes in the nature of the blood. Serologic methods have been confronted by the difficulty that in the preparation of antigens one can hardly ever be absolutely sure that portions of normal tissue have not also been present in the extract. Fuchs' own method, the "Ca R" (cancer reaction), first

published in 1926, follows a different route, in that (1) it makes use of no serologic technique but uses exact chemical analysis, and (2) the standardized reaction substances with which the serums to be examined are incubated have their origin not in the tissue but in the blood. This fact shows clearly, Fuchs thinks, that in the blood of cancer patients there circulates a substance which bears a specific relation to the tumor. There are 2 ways of isolating it: (1) The fibrin formed in connection with spontaneous coagulation reveals it in demonstrable quantities. (2) It is also possible by suitable methods of precipitation to obtain from the serum itself a protein fraction containing it. Prolonged investigations have shown that these substances possess the character of true antigens or antibodies, the former being specific products of the tumor, and the latter in their turn being specific against these antigens. Chemical analysis discloses that between the antigen and its specific antibody reactions occur which have heretofore been demonstrable only by complicated serologic methods. The exact differentiation of the serum under examination became possible when it could be demonstrated that a cancer, a lues, and a tuberculosis serum leave unchanged a cancer, a lues, and a tuberculosis fibrin, respectively, while changing all other kinds of fibrin. The cancer reaction is strongly specific, and possesses the property of revealing the cancer in a very early stage, although it gives no hint of its site or type. From the strength of the reaction, which can be recognized by the difference in rest nitrogen, it is possible to determine the relation between the power of the tumor and the degree of resistance offered by the organism.

Treatment of Pott's Fracture,-David Goldblatt bases his paper on an analysis of fifty consecutive unselected personal cases, defining this as one in which there is a fracture of the lower end of the fibula associated with a tear of the internal lateral ligament or an avulsion of the tip of or of the entire internal malleolus with or without a lateral or posterior dislocation of the foot. The fracture is essentially one of adult life, for the trauma producing it at this time of life would cause an epiphyseal separation of the lower end of the tibia in a child. Displaced fractures in this region require meticulous reduction and alignment to restore the action of the joint and prevent dysfunction that may follow poorly or irregularly healed cartilage as a result of incorrect coaptation. Where maintenance of reduction is difficult one should suspect a fracture of the tibial malleolus or a tearing away of the posterior lip of this bone. This may call for skeletal traction. In the case of a non-dis-

placed fracture, or after reduction of a displaced one, retention is obtained by a moulded plaster-of-Paris splint, consisting of a posterior and internal lateral part running from just below the knee and including the foot. This is greatly to be preferred to a circular encasement in that it permits visual and tactile inspection of the fracture site and promotes early passive activity. Physical therapy is an integral part of the treatment and should be concomitant with, rather than subsequent to, immobilization. A joint is as strong as the component muscles that mobilize it, and early restoration of muscle and tendon activity means lessened incapacity of the joint. Function may be consistent with deformity in a shaft fracture but decidedly not in a joint fracture. treatment of a Pott's fracture, the author concludes, is by no means a closed chapter, and poor results may follow even when it is entrusted to hands specially trained to deal with it.—Annals of Surgery, December, 1932, xcvi,

Pericardial Effusion.—Paul D. Camp and Paul D. White have studied the clinical and pathological data on the 126 cases of pericardial effusion containing over 100 c.c. of pericardial fluid found at post-mortem examination at the Massachuseits General Hospital over a period of ten years (1921 to 1930, inclusive). This number occurring among 95,542 cases admitted to the hospital and among 1,729 necropsies. They also included similar data from the Massachusetts Eye and Ear Infirmary, in a series of 71,334 admissions and 109 necropsies. 2 cases showing 100 c.c. or more of pericardial fluid, and also clinical data on 15 cases in which the pericardial paracentesis established the diagnosis of pericardial effusion. The post-mortem cases were divided into three groups, those with 100 to 200 c.c. of pericardial fluid, cases with 250 to 500 c.c. and those with 500 c.c. and The predominant etiological factor in the cases with pericarditis was infection of some type; uremia was a rare cause. In cases without pericarditis the predominant etiological factor was chronic passive congestion or infection elsewhere in the body. Pain was present in 24 of the 126 cases of the post-mortem series at the Massachusetts General Hospital, dyspnea in 68, orthopnea in 37; distended cervical veins were noted in 5, pericardial friction rub in 8, distant heart sounds in 29, and the pulsus paradoxus in 1 case. In the Roentgen examination of 49 cases a correct diagnosis was made once and questioned in 3 other cases. In the 126 cases a correct clinical diagnosis was made only six times; of these 4 had pericarditis with an effusion of 100 to 250 c.c., while 2 had an effusion of over 500 c.c. The clinical group of 15 cases in which a pericardial paracentesis established the diagnosis was instructive since it was made up of patients who presented the clinical signs of effusion to a much greater degree than did the post mortem cases From one of this group 650 cc of fluid were obtained by paracentesis immediately post morteni, while during life paracentesis had yielded much smaller amounts. Since this pa tient presented signs and symptoms similar to the others in this group, and even larger amounts were obtained in others, it was believed that every one of these cases had over 500 cc of pericardial fluid From the data collected it may be concluded that in the ab sence of acute fibrinous pericarditis, the diagnosis of pericardial fluid is likely to be missed unless the effusion amounts to over 500 cc To establish a diagnosis of pericardial effusion all symptoms must be carefully looked for and analyzed and Roentgen ray studies employed -American Journal of the Medical Sciences, December, 1932, classes, 6

The Hematopoietic Response in Pernicious Anemia Following the Intramuscular Injection of Gastric Juice-Castle and his coworkers (1931) demonstrated that the feeding of beef digested in normal gastric juice to patients with pernicious anemia caused a reticulocyte response, while gastric juice without beef was ineffective. As a result of these researches, it seemed to the authors of this paper (Roger S Morris, Leon Schiff, George Burger, and lames E Sherman) that possibly the normal stomach secreted the substance which Castle had shown to be present, and that while without effect when administered orally, it might cause a response if given parenterally several attempts they succeeded in preparing a concentrated normal human gastric juice. This they first tested in rabbits and then give to patients with permicious anemia. The intramuscular injection of the equivalent of 450 c c of gastric juice to a patient with 2 100 000 red cells led to a reticulosis of 176 per cent in 36 Twelve days after the injection the red count and percentage of hemoglobin began to increase, within the next twelve days the count increased by 1,500 000 cells and the hemoglobin by 20 per cent The count then remained stationary until further treatment was instituted. A second patient, in whom the red count could not be raised beyond a certain level with intensive treatment with liver extract responded to the injection of human gastric juice the red count increasing from 4,100,000 to 5,100 000 and the hemoglobin from 76 to 88 per cent within fourteen days These results proved the presence in normal gastrie juice of a powerful bone marrow stimulant which produced not only a marked and rapid reticulocyte increase but also rapid maturation

of the red cells The authors found that this anti-anemic substance of gastric juice was thermolabile, dialysable, and exhaustible is probably a hormone for which they propose the name addisin, after Thomas Addison, who first described pernicious anemia. They have given 62 intramuscular injections of this substance, in amounts of from 5 to 25 cc rather severe reactions followed the injection of human gastric juice, acetone extracted swine tuice was used instead. This has produced practically no febrile reaction and the pain has been much less and of shorter duration seems highly probable that the temporary lack of addisin in the gastric juice is the cause of pernicious anemia -American Journal of the Medical Sciences, December, 1932, clxxxix, 6

Bacteria on Fruit - J T Smeall, writing in the British Medical Journal, November 19, 1932, n, 3750, notes a failure, in connection with the slogan "Eat more fruit," to draw the attention of the public to the fact that raw fruit is rife with microorganisms. In a recent report of the Medical Research Council there occurs the statement, "Bacteria, moulds and yeast are common on the surface of fruit," but there is no hint as to the nature of these bacteria. In an investigation as to the type of these organ isms, Smeall examined dates, grapes and cher Sixteen examinations of Tunis dates showed B subtilis and allied organisms 16 times streptococci 16 times, yeast 8, B coli 7 and staphylococci 7 times. In 20 examinations of grapes B subtilis and allied organisms were isolated 20 times, streptococci 19, staphylococci 6 times and moulds once Ten examinations of cherries gave quite similar results. The types of streptococci most frequently found were S faccalis, S mitis and S salivarius. It may be accepted as a fact that all raw fruits exposed for sale are vehicles of bacteria. Fortunately the vast majority of germs attached to the surface of fruit are quite harmless However, 1t seems not unreasonable to suppose that at least some of the minor intestinal disturbances that are common in the fruit-eating season may be due to the bacteria content of the fruit Germs present on the surface do not penetrate through the unbroken skin to the edible pulp Typhoid bacilli may be carried on the surface of fruit, and Bindseil found that their life expectancy was longer on the outside than on the cut surface of fruits, this is thought to be due to the acid content of the pulp Some writers hold that the only method which will kill all pathogenic bacteria and at the same time proto zoan cysts and helminth eggs is the dipping of fruits in boiling water for ten seconds Smeall says it is sufficient to minimize the risk of infection that fruit be washed in running water or several changes of water

LEGAL

AUTOPSY—HOSPITAL HELD NOT RESPONSIBLE FOR AUTOPSY PERFORMED BY MEDICAL EXAMINER

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York.

An interesting case in which a claim was made by the relatives of a deceased person against a hospital, based upon an alleged unlawful autopsy, was recently the subject of judicial decision by one of the Judges of our New York Supreme Court. The facts, briefly, were as follows:

A youth, about seventeen years of age, was brought into one of the larger metropolitan hospitals for care and treatment. The boy was examined thoroughly on entrance, and the history obtained revealed a weakness in the cardiac region which had extended over a period of four years and a persistent condition of diarrhea for three years, with a loss of weight of thirty-three pounds during the four-year period. The diagnosis on admission was ulcerative entero colitis of tuberculous origin, complicated by thrombosis of the longitudinal sinus.

The patient was put in one of the wards where he was seen and treated daily over a period of approximately two weeks by several staff physicians. During this time the patient at intervals suffered from hallucinations, one of which was to the effect that he had been poisoned. He would also, from time to time, lapse into a comatose condition. The course of his condition at the hospital was very puzzling. Repeated pathological tests were made including blood, stool and spinal fluid, and numerous X-rays were taken. The reports were inclusive as to the cause of his condition. His pulse and temperature fluctuated in an unusual manner throughout. In spite of all efforts to treat the patient's maladies, about two weeks after his admission into the hospital the patient died. The doctor in charge of the case was unable to state definitely the cause of death. This physician, mindful of the repetition by the boy of statements as to poisoning, thereupon advised his superior who, in turn, notified the office of the medical examiner of the City of New York. Pursuant to this notice of suspicious death, one of the assistant medical examiners went to the defendant hospital and there performed an autopsy upon the body. The autopsy was a negative one, revealing no untoward circumstances and in general confirming the diagnosis which had been made at the hospital before the boy's death.

About a year after the boy's death, his father instituted an action against the hospital to recover \$15,000 damages. The complaint charged that the plaintiff's son was brought to the hospital as a

patient for treatment and that he there died. No negligence was charged in connection with the treatment of the boy while he was alive, but the complaint charged that after the death the hospital authorities asked for a consent to an autopsy which was expressly refused, and that in the face of said refusal the medical examiner was requested by the hospital authorities to perform an autopsy upon the boy's body. It was also alleged that the body was thereby mutilated, cut and disfigured in violation of the duty of the hospital to deliver to the parents their son's body in the same condition as it was at the time of his death. It was claimed that the said acts were a wilful outrage of the plaintiff's rights and sensibilities, and that the shock of the sight of his son's mutilated body caused him to suffer great mental anguish. It was further claimed that the deceased was of the Orthodox Jewish Faith, and that said Faith required burial of the deceased's body intact, and that the plaintiff's religious feelings had been greatly outraged by said alleged acts on the part of the defendant hospital.

The answer interposed on behalf of the hospital set up as a special defense that the autopsy had been performed by one of the assistant medical examiners of the City of New York pursuant to his duties as prescribed by law.

On the trial of the action the father testified that he had been asked by a doctor on the staff of the hospital, after the demise of his son, whether he would consent to an autopsy to determine the cause of death. The father testified that he had refused, giving as his reason that he was of the Jewish Faith, and that the tenets of his religion did not approve of dissection of the body after The assistant medical examiner who performed the autopsy was called as a witness for the plaintiff and testified that pursuant to instructions he had gone to the defendant hospital, and after examining the charts, history and bedside notes decided that in his opinion this was a case wherein an autopsy should be performed. Said assistant medical examiner predicated his opinion on the fact that this boy had been suffering from chronic diarrhea and had had hallucinations as to being poisoned, together with the fact that none of the doctors who had treated him were able to determine definitely the cause of death. When interrogated regarding the diarrhea, the doctor stated that the history of that condition raised in his

LEGAL

mind the possibility that probably the boy had had a chronic toxic condition extending over a long period of time. The doctor further gave as his opinion that, in the light of all the circumstances, this was a case where an autopsy should have been performed, and that he did so perform it in his capacity as an assistant medical examiner of the City of New York, thereby negativing the neces-

sity of consent from the parent. No other witnesses were called by the plaintiff, and when he had rested his case a motion was made by counsel for the defendant to dismiss the complaint on the ground that the plaintiff had failed to establish his cause of action, i.e., unlawful autopsy on the part of the defendant hospital. In granting this motion, the Trial Judge stated

his view of the case as follows:

This action is brought by the plaintiff in his own right as the next of kin of his deceased son, X. 'The son died in the hospital on January 30, 1926.

It appears that the hospital authorities requested permission to perform an autopsy on the body of X, and

permission was refused.

"It is well settled, that in the absence of a contrary testamentary disposition, the right of the possession of the body of one who has died belongs to the surviving husband or wife or next of kin for the purpose of preservation and burial; and that this right is infringed upon by anyone who unlawfully mutilates such a body without the consent of the person entitled to the possession of it. For a violation of this right, damages may be recovered for the injury to the feelings and the mental suffering resulting from the unlawful act. In all of the cases, however, in which such a right of action has been upheld, the one held liable has either been the one who committed that unlawful act or one who caused or procured the autopsy to be made.
"The undisputed evidence here is that the office of the

medical examiner in Brooklyn sent word to or called the main office in the Borough of Manhattan and pursuant to that call an assistant medical examiner, Dr. A, went to the hospital, where he, and he alone, took charge of

the body.

"The question of autopsies, and when they may be performed, is covered by definite statute embodied in sec-Those provisions have been added to by the laws of 1915 which abolished in this city the offices of coroner theretofore existing.

"In substance, section 1570-A of the charter provides

"When in the City of New York any person shall die in any suspicious or unusual manner, notice shall be given to the office of the chief medical examiner and immediately upon receipt of such notification, the chief

medical examiner or a deputy or assistant medical examiner shall go to the dead body and take charge of it.' "And then provides for a full investigation into the

essentlal facts.

"Section 1571-A of the charter provides that if the cause of death is established beyond a reasonable doubt, a medical examiner in charge shall so report to his office.

"In this case the hospital records indicated that the cause of death was unknown; attendant upon which, were the further facts evidenced by the hospital record in evidence as Plaintiff's Exhibit 1 that this patient had suffered from diarrhea for a period of about three years; and while in the hospital had hallucinations that he had been poisoned; taken together, Dr. A, the assistant medical examiner testified that those might be evidence of poisoning and that because of it he and he alone ordered an autopsy and took charge of it.

"Section 1571-A of the charter further provides that if, in the opinion of such medical examiner, an autopsy is necessary, the same shall be performed by the medical examiner; and further makes provisions for a detailed description of the findings as written during the progress of such autopsy, and the conclusions drawn therefrom are all required to be filed in his office. This latter was done, and this report is in evidence as Plaintiff's Exhibit 2.

"The plaintiff is of the Orthodox Jewish Faith. Whatever may be the religious belief of a citizen of this State, for a violation of that faith by a public authority in the performance of his duty, there is and can be no right of action.

"A member of the Mormon Church may believe that he is entitled to a plurality of wives, but the United States Supreme Court has held that in the face of the bigamy statute, though he may continue to believe this, he cannot have the wives. We have to be sincere and must give way in the material to the sociological and scientific progress, and especially so when such progress is in the interest of the public health and safety,

Autopsics serve the dual purpose of ascertaining the facts of this death, as a basis for preventive action, and likewise the ascertainment of facts in the scarch for crime

where the possibility of crime is present,

"Naturally, the cases on this subject are few. In this case the claim for damages is based on the allegation that after the boy's death the father's tender feelings, which I deeply respect and sincerely sympathize with, were violated by the defendant hospital; but it is too plain for argument that the act here complained of was in no sense the act of the defendant hospital; it was the act of a public officer, namely, the assistant medical examiner, done in the performance of his duty.'

The result reached is not only in accordance with sound public policy but in accordance with the principles of law applicable to cases of this character. The decision is interesting because of the dearth of authority upon the point involved.

INCONTINENCE OF URINE FOLLOWING OPERATION

A married woman about 37 years of age who had been receiving treatments for several months in the out-patient department of a large hospital was referred to a certain member of the surgical staff of said hospital for operative treatment.

The provisional diagnosis was that of second degree laceration of the pelvic floor, cystocele, rectocele and retroversion of the uterus. said surgeon and two of his assistants examined

the patient thoroughly and made a preoperative diagnosis of cystocele, rectocele, laceration of the pelvic floor, hypertrophied lacerated infected cervix and visceroptosis. An operation to correct the said conditions was undertaken. The patient was brought into the operating room under a gas ether anesthesia. The doctor began the operation by grasping the cervix with tenacula, drawing the uterus down to a point allowing its direct inspection, incision of tisues by circular strokes through the vagina and adjacent tissues close to its cervical attachment to liberate the lower uterine segment and to free the vagina at its uterine contact thus developing a cuff for subsequent plastic work. The doctor separated the bladder and the anterior vaginal wall by a knife and dull dissection. A vertical incision by scissors was made of all vaginal tissues from the free surface of the cuff upward toward the entrance of the urethra. The doctor by dull dissection from the cut edge outward liberated the bladder; he removed a triangular area base downward from each side of this anterior vaginal incision, identified the tissues about the bladder sphincter and introduced a Kelly-stitch for the purpose of splinting the tissues about the relaxed sphincter. The cut edges of the anterior vaginal wall were approximately and these were sutured edge to edge with No. 2 chromic gut, two sutures being passed into the anterior uterine wall to eliminate dead space and further to develop bladder support. The doctor then proceeded to a stage of the operation which consisted of conical enucleation of chronically infected and hyperplastic tissue of the cervix and infolding of the vaginal cuff by the method of Sturmdorff. He next exposed the posterior vaginal wall and rectocele by a Blair Bell retractor. He introduced within the rectum a gauze vaseline pack to define the rectocele; applied a clamp to the posterior vaginal wall at a high point of the rectocele; removed the rectal pack and incised into the recto-vaginal space, which recto-vaginal space was then defined by finger dissection downward toward the perineal scar contact of the rectum and vagina; a triangular portion of the posterior vaginal wall over the recto-vaginal space was incised and removed. This removed area included patulous and thinned out vaginal tissue and scar. This removal allowed direct inspection of the rectum which was prolapsed and attentuated. This organ was then elevated by introducing a No. 2 chromic gut suture above the clamp on the pinnacle of the rectocele, carrying suture downward to the most prominent area of the redundant rectum, across the bowel in fractional stitches through this dilated protruding area, then upward and through the posterior vaginal wall near the point of original entrance and traction on this suture elevated and puckered the herniated rectum thus doing away with one element of the rectocele. The triangular opening in the posterior vaginal wall was then closed by approximating its cut edges followed by suture union of the separated levator muscles, then by approximation of the overlying fascia and finally by closure of the perineal skin by subcutaneous stitches.

The doctor saw the patient, as was his custom, for only a few days after the operation, she having been referred to him as a charity patient for operation only. The patient remained at the hos-

pital for nearly three weeks and was discharged in satisfactory condition, her progress subsequent to the operation having been good with no bad results developing prior to her discharge.

The patient returned to the follow-up clinic at the hospital at which time she was examined by other members of the hospital staff. About a month after her discharge examination at the said clinic showed that she was cured of her preoperative complaints, except that a condition of incontinence of urine was present. About a month after said examination a subsequent cystoscopic examination showed a mild bilateral kidney infection with a mild trigonitis and cystitis which was believed to be the cause of patient's incon-She received clinic treatment for her condition and when last seen at the hospital, at a date about six months subsequent to the operation, she was still complaining of incontinence and at that time it was suggested that she should enter the hospital as a ward patient and receive observation and surgical repair.

The patient did enter the hospital for observation, and a cystoscopic examination performed at that time by doctors associated with the hospital staff enabled the said doctors to diagnose that the cause of her incontinence was a urethro-vaginal fistula. An operation was suggested but the patient refused the operation and left the hospital.

Thereafter an action was instituted against the surgeon, charging him with malpractice in the performance of the operation upon the plaintiff, and claiming that as a result of his negligence in said operation the patient suffered from a persistent and constant leakage of urine, the result of a urethrovaginal fistula. The plaintiff's bill of particulars also claimed that the vesicle sphincter muscle was partly or completely destroyed by reason of defendant's negligence. Said injuries were claimed to be of a permanent and progressive nature.

At the time the case was reached for trial the defendant was severely ill and an application was made to postpone the trial of the case until the defendant could appear in court and testify in his own behalf. Said application was granted to the extent that a short adjournment was allowed. When the case again came up on the calendar for trial the defendant doctor's condition had not sufficiently improved that he could appear in court and testify, and another application was made to adjourn the trial of the case. The plaintiff's attorney insisted on proceeding to trial and the Judge was not willing to grant a second adjournment. The doctor's testimony was therefore taken by deposition at his bedside, and immediately after the taking of said deposition the case proceeded to trial. The issues in the case were submitted by the court to the jury and a verdict of no cause of action was rendered by them, thereby exonerating the doctor from all charges of negligence in the performance of the operation.

NOTES NEWS

THE COUNCIL MEETING

A meeting of the Council of the Medical Society of the State of New Ynrk was held in the rooms of the Society, 2 East 103rd Street, New York, on the afternoon of Thursday, December 8, 1932. in accordance with the By-laws of the State Society, Chapter IV, sections 1 and 2, which read:-

"The Council shall meet at the annual meeting of the House of Delegates, It shall meet twice a year, the time and place to be

selected by the President."

It has been the custom of the Council to hold its special meeting at the time and place of the regular monthly meeting of the Executive Committee in December. The Council is composed of 31 members as provided in Article IV of the Constitution, which reads:-

"The Council shall be composed of

(a) Officers of the Society

(b) Chairmen of the Standing Committees

(c) The Editor-in-Chief

(d) The retiring President for a term of one year after his term of office expires."

There is now one vacancy owing to the death of Dr. John A. Card, Speaker of the House of Delegates. Twenty-six members attended the last meeting, as follows:-

President, Dr. Chas. Gordon Heyd President-elect, Dr. Frederick H. Flaherty Past-President, Dr. W. D. Johnson First Vice-President, Dr. A. S. Chittenden Assistant Secretary, Dr. Peter Irving Treasurer, Dr. Frederic E. Sondern Vice-Speaker, Dr. George W. Cottis Trustee, Dr. A. W. Booth

Dr. N. R. Van Etten "

Dr. Grant C. Madill " Dr. Harry R. Trick

Dr. James F. Rooney

Chairmen of Standing Committees:-

Dr. Arthur J. Bedell

Dr. Samuel J. Kopetzky

Dr. Thomas P. Farmer

Dr. Harry Aranow

Dr. Charles H. Goodrich

Dr. James E. Sadlier

Presidents of District Branches:-

Dr. Louis A. Van Kleeck

Dr. Herbert L. Odell

Dr. Frank Vander Bogert

Dr. Edward R. Evans

Dr. James M. Flynn

Dr. Raymond B. Morris

Dr. Charles D. Kline

Editor-in-Chief: Dr. Orrin S. Wightman.

Several important questions were discussed by the Council at length. Decision in each instance awaits further study. One of these questions was the revision of the rules concerning malpractice defense. This matter has been previously discussed and the rules tentatively formulated, but further and careful study in several minor details will be necessary before final decision.

The report of the National Committee on the Costs of Medical Care was discussed. The Couneil decided that it did not possess the knowledge requested for action, since no copies of the report were available for general distribution. It was voted to appoint a special Committee to study the report and to suggest a line of action for the consideration of the State Society. The Committee named consists of-

Dr. A. W. Booth, Elmira, Chairman

Dr. James F. Rooney, Albany

Dr. N. B. Van Etten, Bronx

Dr. George W. Cottis, Jamestown

Dr. S. J. Kopetzky, New York Dr. C. H. Goodrich, Brooklyn

Dr. E. E. Haley, Buffalo

The Council adopted a resolution thanking the New York Herald Tribune for its editorial of December 4, in favor of the present individual method of giving medical service, in contrast with an insurance system. (This editorial was reproduced on page 1438 of this Journal of December 15, 1932.)

The meeting of the Council was of great value in securing information and expressions of opinions from medical leaders from all parts of the State.

tion, incision of tisues by circular strokes through the vagina and adjacent tissues close to its cervical attachment to liberate the lower uterine segment and to free the vagina at its uterine contact thus developing a cuff for subsequent plastic work. The doctor separated the bladder and the anterior vaginal wall by a knife and dull dissection. A vertical incision by scissors was made of all vaginal tissues from the free surface of the cuff upward toward the entrance of the urethra. The doctor by dull dissection from the cut edge outward liberated the bladder; he removed a triangular area base downward from each side of this anterior vaginal incision, identified the tissues about the bladder sphincter and introduced a Kelly-stitch for the purpose of splinting the tissues about the relaxed sphincter. The cut edges of the anterior vaginal wall were approximately and these were sutured edge to edge with No. 2 chromic gut, two sutures being passed into the anterior uterine wall to eliminate dead space and further to develop bladder support. The doctor then proceeded to a stage of the operation which consisted of conical enucleation of chronically infected and hyperplastic tissue of the cervix and infolding of the vaginal cuff by the method of Sturmdorff. He next exposed the posterior vaginal wall and rectocele by a Blair Bell retractor. He introduced within the rectum a gauze vaseline pack to define the rectocele; applied a clamp to the posterior vaginal wall at a high point of the rectocele; removed the rectal pack and incised into the recto-vaginal space, which recto-vaginal space was then defined by finger dissection downward toward the perineal scar contact of the rectum and vagina; a triangular portion of the posterior vaginal wall over the recto-vaginal space was incised and removed. removed area included patulous and thinned out vaginal tissue and scar. This removal allowed direct inspection of the rectum which was prolapsed and attentuated. This organ was then elevated by introducing a No. 2 chromic gut suture above the clamp on the pinnacle of the rectocele, carrying suture downward to the most prominent area of the redundant rectum, across the bowel in fractional stitches through this dilated protruding area, then upward and through the posterior vaginal wall near the point of original entrance and traction on this suture elevated and puckered the herniated rectum thus doing away with one element of the rectocele. The triangular opening in the posterior vaginal wall was then closed by approximating its cut edges followed by suture union of the separated levator muscles, then by approximation of the overlying fascia and finally by closure of the perineal skin by subcutaneous stitches.

The doctor saw the patient, as was his custom, for only a few days after the operation, she having been referred to him as a charity patient for operation only. The patient remained at the hos-

pital for nearly three weeks and was discharged in satisfactory condition, her progress subsequent to the operation having been good with no bad results developing prior to her discharge.

The patient returned to the follow-up clinic at the hospital at which time she was examined by other members of the hospital staff. About a month after her discharge examination at the said clinic showed that she was cured of her preoperative complaints, except that a condition of incontinence of urine was present. About a month after said examination a subsequent cystoscopic examination showed a mild bilateral kidney infection with a mild trigonitis and cystitis which was believed to be the cause of patient's incontinence. She received clinic treatment for her condition and when last seen at the hospital, at a date about six months subsequent to the operation, she was still complaining of incontinence and at that time it was suggested that she should enter the hospital as a ward patient and receive observation and surgical repair.

The patient did enter the hospital for observation, and a cystoscopic examination performed at that time by doctors associated with the hospital staff enabled the said doctors to diagnose that the cause of her incontinence was a urethro-vaginal fistula. An operation was suggested but the patient refused the operation and left the hospital.

Thereafter an action was instituted against the surgeon, charging him with malpractice in the performance of the operation upon the plaintiff, and claiming that as a result of his negligence in said operation the patient suffered from a persistent and constant leakage of urine, the result of a urethrovaginal fistula. The plaintiff's bill of particulars also claimed that the vesicle sphincter muscle was partly or completely destroyed by reason of defendant's negligence. Said injuries were claimed to be of a permanent and progressive nature.

At the time the case was reached for trial the defendant was severely ill and an application was made to postpone the trial of the case until the defendant could appear in court and testify in his own behalf. Said application was granted to the extent that a short adjournment was allowed. When the case again came up on the calendar for trial the defendant doctor's condition had not sufficiently improved that he could appear in court and testify, and another application was made to adjourn the trial of the case. The plaintiff's attorney insisted on proceeding to trial and the Judge was not willing to grant a second adjournment. The doctor's testimony was therefore taken by deposition at his bedside, and immediately after the taking of said deposition the case proceeded to trial. The issues in the case were submitted by the court to the jury and a verdict of no cause of action was rendered by them, thereby exonerating the doctor from all charges of negligence in the performance of the operation.

x-rays among families which caunot pay for the service, and the holding of 50 diagnostic tuberculosis clinics aside from other clinics. The voluntary association supplements the program of
medical profesion in this county to the extent of
six cents per capita. This would make the total
outlay \$1.12 per capita independent of State aid.
The entire cost for health services in Suffolk
County is \$170,000 for 160,000 people, plus
\$9,600 contributed by the voluntary Tuberculosis
and Public Health Association.

BRONX COUNTY

Dr. David Greenberg, Chairman of the Public Relations Committee of Bronx County, gave a report on the efforts to bring medical service within the reach of all the people by means of private practitioners. A bedside nursing service has been curtailed during the depression, but it is supplied to the destitute sick in their homes on the presentation of cards from the doctors in atendance. This service takes the place of free clinics.

The physical examinations of high school children are done by physiciaus called by the Principals of the school, from a list supplied by the

County Medical Society.

The basis of all medical service to those unable to make full payment is that all free medical service shall be given through the County Medical Society,

KINGS COUNTY

Dr. A. E. Shipley, Chairman of the Public Relations Committee of the Kings County Society, reported that for ten years or more the Society had emphasized the civic obligations of physicians in the monthly meetings as well as in the activities of its committees. The Society engages Dr. Alec N. Thomson as its Director of Activities on full time, so that the Society has been able to give prompt attention to all its civic obligations. It is now the established procedure that civic organizations, both official and lay, consult the Medical Society in regard to public health appointments and lines of work.

The County Society supplies physicians who examine high school students at twenty-five cents each, the Society receiving the money and paying

each examiner five dollars per hour.

When high schools or other lay organizations want speakers on health, the Public Relations Committee sends them. The Committee also censors radio talks, helps in district health weeks, and ties up the fifteen or more local medical societies with the Kings County Society.

NASSAU COUNTY

Mr. Louis Neff, Executive Secretary of the Nassau County Medical Society, said that the amount of state medicine done in a county was an inverse ratio to the amount of medical leadership in the locality.

The first public health activity of the Nassau County Medical Society was to get in touch with every lay health agency in the county. Every agency now looks to the County Society for advice and leadership.

The Cancer Committee of the County Society is actively functioning with Dr. A. C. Martin as

Chairman.

The County General Hospital was sponsored and promoted by the County Medical Society, and is now half completed.

The Press Relations Committee gives the editors full information and is usually able to kill any story that is against the interests of good medical

service

The Medical Society has appointed a committee to study the report of the Committee on the Costs of Medical Care, and has adopted the policy that members of the County Society shall not make public comments on the report until they have had the opportunity to read and study it.

The Society has made an agreement with the Welfare Commissioner in regard to giving medi-

cal service to the indigent (see page 39).

The Society has made an agreement with the School Men's Association in regard to giving immunizations against diphtheria.

The Society is also cooperating with officials who are administering the State Temporary Relief Funds, and is giving the services in the homes of the poor, using practical nurses if the public

health nurses are not available.

Mr. Neft, being a lay secretary, finds that poor people consult him as lay secretary of the County Society when they would be embarrassed to ask help from a physician. He also spoke of the growth of the idea of lay secretaries for county medical societies. He was the first one to be employed in New York State, but now after ten years there are at least nine more.

QUEENS COUNTY

Dr. Carl Boettiger, Chairman of the Public Relations Committee of Queens County Society, reported that the Society has eight members assigned to lay health organizations prepared to advise and assist them. There is a Welfare Council in Queens County, and the County Society has a representative on its Board, as also has each of the other organizations. The meetings are held in the building of the County Society.

A member of the County Society is on the Board of the Tuberculosis Association, and the Society receives \$1,000 annually from the Association to be spent in anti-tuberculosis work.

The Public Health Education cooperates with the Welfare Council in giving health talks. The County Society conducted a class in public speaking years ago, and the full course was attended by forty doctors who are now enthusiastic and ready to respond to assignments to give health talks to lay organizations.

COMMITTEE ON PUBLIC RELATIONS

A meeting of the Committee on Public Relations of the Medical Society of the State of New York was held on December 9, 1932, in the Hotel Roosevelt with the following members present: Dr. J. E. Sadlier, Chairman; Dr. W. H. Ross, Secretary; Drs. Hambrook, Johnson, and Cunningham; and Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education, Dr. J. S. Lawrence, Executive Officer, and Dr. Frank Overton, Executive Editor.

The morning session was devoted principally to a discussion of the report of the Committee on the Cost of Medical Care, and particularly the recommendations of a majority of the committee as contrasted with those of minority, all of whom are listed in the group of physicians in private practice. The discussion developed the fact that the report had not yet been distributed except a few advance copies, and that no member of the Committee on Public Relations had been able to obtain a copy of the report. The Committee therefore decided to make no comment until its members had had the opportunity to read the report and to give it careful consideration.

The afternoon session was devoted to a regional conference of the Chairman of the Public Relations Committees of the County Societies in the Metropolitan area. Reports were received from representatives of nine societies, as follows:

New York	Kings	Richmond	
Suffolk	Nassau	Rockland	
Bronx	Queens	Westchester	

NEW YORK COUNTY

Dr. Chas, Gordon Heyd, President of the Medical Society of the State of New York, but speaking also for the New York County Society, which contains almost one-third of the membership of the State Society, discussed medical economics, and the conservative yet progressive attitude of the medical profession toward new problems. Physicians have new methods of medical practice and medical administration thrust upon them every day, but their attitude of "investigation before judgment" is that of the truly scientific mind. This attitude will apply particularly to the medical profession in its consideration of the reports of the Committee on the Costs of Medical Care and the Commission on Medical Education.

SUFFOLK COUNTY

Dr. William H. Ross told of the public relations of the medical profession in his home county of Suffolk to other health agencies. The Suffolk County Medical Society is represented on every health agency and organization in the county, and is dominant in every health movement. There are five general hospitals in Suffolk County sup-

ported by public contributions. Each is well equipped for distributing a complete medical service, and is in fact a medical center. Each is an open hospital and each has an organized staff, to which almost the entire profession of the county belongs. The quality of the service in each is controlled by a medical board.

The anti-tuberculosis program in Suffolk County was initiated by the medical profession twenty years ago and ever since has been under its active leadership. The voluntary Tuberculosis and Public Health Association has had a practicing physician at its head ever since its organization eighteen years ago. There have always been several physicians on its Board of Directors. The activities of this organization have always supplemented the activities of the Medical Society.

A County Health Department was established five years ago in this county under the leadership of the County Medical Society. The county has now many health services which it did not have. Public health nursing has been increased five fold. The county has a sanitary engineer, a county laboratory, a veterinary division, an orthopedic division, venereal disease control, a supervising nurse, and an organization of the fifty-six public health, school, Red Cross, and social service nurses with monthly meetings and records of all the work filed with the Health Department.

The county has personnel for milk production inspection, boarding home inspection, wayside eating place inspection, swimming pool and camp inspection, supervision of the practice of midwives, and supervision of maternity homes. The Health Department pays the physicians of the county for treating their own indigent cases of venereal disease.

Diagnostic clinics conducted by members of the local profession are held for tuberculosis, post uatal care, orthopedics, and cancer control. No treatment is given in any of the clinics. All cases are referred to the family physician.

The medical profession cooperates actively in the administration of public welfare. All professional work for the indigent is done by the family physician upon authorization by the County Public Welfare Commissioner. All this work is paid for according to a standard fee list set up by the County Medical Society and the Commissioner of Public Welfare, at average fees prevailing in private practice in the county. All hospitals are paid a per diem fee of \$3.50. Doctors are paid whether the patient is cared for at home, in the office, or in the hospital. The Economic Committee of the County Society acts as a board of arbitration in all disputed matters between physicians and the Commissioner of Public Welfare.

The cost of public health in Suffolk County is \$1.06 per capita. It includes the maintenance of the Tuberculosis Sanatorium for one hundred patients, the taking of more than 1,200 diagnostic

x-rays among families which cannot pay for the service, and the holding of 50 diagnostic tuber-culosis clinics aside from other clinics. The voluntary association supplements the program of medical profesion in this county to the extent of six cents per capita. This would make the total outlay \$1.12 per capita independent of State aid. The entire cost for health services in Suffolk County is \$170,000 for 160,000 people, plus \$9,600 contributed by the voluntary Tuberculosis and Public Health Association.

BRONX COUNTY

Dr. David Greenberg, Chairman of the Public Relations Committee of Bronx County, gave a report on the efforts to bring medical service within the reach of all the people by means of private practitioners. A bedside nursing service has been curtailed during the depression, but it is supplied to the destitute sick in their homes on the presentation of cards from the doctors in atendance. This service takes the place of free elinics.

The physical examinations of high school ehildren are done by physicians called by the Principals of the school, from a list supplied by the

County Medical Society.

The basis of all medical service to those unable to make full payment is that all free medical service shall be given through the County Medical Society.

KINGS COUNTY

Dr. A. E. Shipley, Chairman of the Public Relations Committee of the Kings County Society, reported that for ten years or more the Society had emphasized the eivic obligations of physicians in the monthly meetings as well as in the activities of its committees. The Society engages Dr. Alec N. Thomson as its Director of Activities on full time, so that the Society has been able to give prompt attention to all its eivic obligations. It is now the established procedure that civic organizations, both official and lay, consult the Medical Society in regard to public health appointments and lines of work.

The County Society supplies physicians who examine high school students at twenty-five cents each, the Society receiving the money and paying

each examiner five dollars per hour.

When high schools or other lay organizations want speakers on health, the Public Relations Committee sends them. The Committee also censors radio talks, helps in district health weeks, and ties up the fifteen or more local medical societies with the Kings County Society.

NASSAU COUNTY

Mr. Louis Neff, Executive Secretary of the Nassau County Medical Society, said that the amount of state medicine done in a county was an inverse ratio to the amount of medical leadership in the locality.

The first public health activity of the Nassau County Medical Society was to get in touch with every lay health agency in the county. Every agency now looks to the County Society for advice and leadership.

The Cancer Committee of the County Society is actively functioning with Dr. A. C. Martin as

Chairmai

The County General Hospital was sponsored and promoted by the County Medical Society, and

is now half completed.

The Press Relations Committee gives the editors full information and is usually able to kill any story that is against the interests of good medical service.

The Medical Society has appointed a committee to study the report of the Committee on the Costs of Medical Care, and has adopted the policy that members of the County Society shall not make public comments on the report until they have had the opportunity to read and study it.

The Society has made an agreement with the Welfare Commissioner in regard to giving medi-

cal service to the indigent (see page 39).

The Society has made an agreement with the School Men's Association in regard to giving im-

munizations against diphtheria.

The Society is also cooperating with officials who are administering the State Temporary Relief Funds, and is giving the services in the homes of the poor, using practical nurses if the public health nurses are not available.

Mr. Neff, being a lay secretary, finds that poor people consult him as lay secretary of the County Society when they would be embarrassed to ask help from a physician. He also spoke of the growth of the idea of lay secretaries for county medical societies. He was the first one to be employed in New York State, but now after ten years there are at least nine more.

QUEENS COUNTY

Dr. Carl Boettiger, Chairman of the Public Relations Committee of Queens County Society, reported that the Society has eight members assigned to lay health organizations prepared to advise and assist them. There is a Welfare Council in Queens County, and the County Society has a representative on its Board, as also has each of the other organizations. The meetings are held in the building of the County Society.

A member of the County Society is on the Board of the Tuberculosis Association, and the Society receives \$1,000 annually from the Association to be spent in anti-tuberculosis work.

The Public Health Education cooperates with the Welfare Council in giving health talks. The County Society conducted a class in public speaking years ago, and the full course was attended by forty doctors who are now enthusiastie and ready to respond to assignments to give health talks to lay organizations.

The Committee is paid by the Chamber of Commerce to make a survey of the health service given by industrial plants, of which there are a great number in the county.

RICHMOND COUNTY

Dr. H. A. Cochrane, Chairman of the Public Relations Committee of the Richmond County Society (Staten Island) reported that the county is almost rural, and is in a transitional stage of development, being isolated from both New York City and New Jersey; and the people lack cohesion. The County Society has 99 members, but it is trying to place a representative in every welfare and public health organization.

ROCKLAND COUNTY

Dr. R. F. Sengstacken, of Rockland County, reported that his county is small, but that its Medical Society has 56 members, for nearly every

doctor in the county belongs to it. Eleven of the doctors are on the paid staffs of public institutions, and forty-five are in private practice.

The Society has taken an active interest in public relations during the past two years, and has succeeded in placing a member on the Board of

every welfare organization.

The County Society is planning to make a careful study of the report of the Committee on the Costs of Medical Care, and to devote a meeting to its discussion.

WESTCHESTER COUNTY

Dr. C. C. Guion, Chairman of the Westchester County Public Relations Committee, gave an outline of the report of the Committee which it had made to the County Society describing the development of the hospital in New Rochelle as the medical center of the City, which contains about 50,000 people. (See the following article.)

PUBLIC RELATIONS COMMITTEE OF WESTCHESTER COUNTY

The Public Relations Committee of the Westchester County Medical Society begs to submit the following report of its activities during the year ending November 15, 1932.

When this committee started its activities a year ago, it took up the work of its predecessor and carried it on along the three lines that had already been proposed, namely:-

- 1. To develop the hospital as a medical center.
- 2. To prevent the abuse of the dispensary.
- 3. To provide service for those unable to pay full fees.
- (1) The committee has tried to develop in each community where it is possible, the idea that the hospital is the Medical Center in that community. In New Rochelle, a suburban city of 54,000 inhabitants, northeast of New York, where the chairman resides, we have repeatedly brought this thought to the medical men at staff meetings and society meetings. We have urged the doctors to broadcast to the public that in any emergency where a physician is needed, and where the services of the family physician cannot be secured, if the hospital is advised by telephone, the hospital will endeavor to secure a physician for the case. We have arranged with the hospital to supply the physician at any time with any special form of treatment he may find necessary, whether it be a hospital bed for a decompensated heart, an oxygen tent for a pneumonia patient, glucose solutions for intravenous use, or hypodermoclysis, etc., etc. No matter at what time of day or night the necessity arises, physicians are able to secure any emergency treatment desired, thus making it possible for them to treat their patients at home, with

the result that in many cases the patient is retained under the care of the family physician, or is spared unnecessary expense of hospitalization. We believe that eventually a registry for nurses will be established in the hospital. By these measures we believe that the people will realize that in any emergency, whether they need a doctor, a nurse, or some special form of treatment, the hospital stands ready and willing to serve them.

(2) The committee has endeavored to develop such measures as are possible to protect the doctor in his work, by preventing the abuse of the dispensary. This is only possible by the use of a social service worker investigating such cases as the admitting clerk feels should be investigated. We are all aware of the abuse of the dispensary, and know the financial loss to both physician and hospital that this abuse entails. In but a few of the hospitals in the county is a social service worker employed, but in New Rochelle the hospital governors gladly granted us this service, and the department has been gradually developing in efficiency. Our clinic in New Rochelle, due to the character of our population, is not as large as it is in other localities, but, nevertheless, we have approximately 1,500 visits a month, of which 300 to 400 represent new cases. It is, of course, an impossibility for one worker to make a thorough investigation the financial condition of all these new cases; and accordingly she investigates only such cases as the admitting nurse refers to her. But, when the social worker reports that in one month recently she investigated 83 cases and considered only 35 as eligible for clinic care, one can realize the importance of this work. Please realize also that no case is ever refused treatment for any

emergency, but, if investigation shows that the patient is able to pay for medical care, that person is simply told not to return. Also understand that in these times any doubtful case is always given the benefit of the doubt. There is no desire to refuse treatment to any worthy individual, but the hospital is not warranted in spending the money of its contributors on those who are able to pay for their care, and the physicians should likewise not be compelled to serve those who are not entitled to receive this service.

(3) The committee has endeavored to provide for the care of those who, because of their financial condition are unable to pay the usual fee of a doctor for the service required, yet are jueligible for dispensary treatment. This has been accomplished by an arrangement with the various departments of the clinic whereby the doctors attending their clinics agree to treat such cases, after investigation by the social service worker, at a fee which is within the means of the patient.

It is true that thus far the work of this committee has scarcely caused a ripple on the troubled sca that at present faces the medical man, the hospital, and those unable to pay the usual medical fees. But we believe that what we have done represents a few steps in the right direction; and we urge the committee that succeeds us to carry ou this work and extend it along the lines that have already proved successful. We believe that much can be done to protect the doctor, develop a better feeling for the hospital in its individual locality, and render efficient medical care for those in restricted financial condition.

We suggest to our new President that in the future this committee consist of representatives of the medical boards of the several hospitals, as, thereby, each medical board would become posted with the work of the committee and be able to suggest to the governors of its own hospital such changes as the committee may deem advisable.

C. C. GUION, Chairman.

PUBLIC HEALTH LABORATORIES ASSOCIATION

The following is a condensed report on the use of laboratory facilities by practising physicians of New York State, made by a special committee of investigation appointed by the New York State Association of Public Health Laboratories at its annual meeting on May 23, 1932.

Various considerations had suggested the possibility that in cases of communicable disease either more prompt and accurate reports by laboratories, or more alert and intelligent use of available facilities by practising physicians, might strengthen the public health work of the State. Such considerations as the following had suggested the advisability of exploring this problem: (1) The surprisingly large number of positive Wassermann reactions encountered in institutions where the test is made routinely on all pa-(2) The relatively high percentage of cases of tuberculosis reported as 'far advanced' and 'moderately advanced' when the case is first reported. (3) Outbreaks of diarrhea and food poisoning without the nature and source of infection being discovered. (4) The frequency with which a long interval occurs between the initial symptoms of a disease and the conclusive diagnosis, identification of carrier, or the discovery of the source of infection.

The Importance of the Problem, and the Probable Causes for Its Existence.—From the investigations of the Committee it appears that there is practically no difference of opinion as to the existence of a condition relating to the use of laboratory facilities which leaves room for improvement. It is further evident that conditions vary widely in different localities. In some districts nearly all of the physicians make intelligent use of the laboratory facilities, the laboratory is prompt and accurate in its reports, and there is

au excellent spirit of cooperation between the laboratory and the practising physicians. In other localities as many as 60% of the physicians apparently make little or no use of the available The consensus of opinion may be facilities. roughly summarized as follows: About 50% make full use of available laboratory facilities, about 30% to 40% make moderate use, and 10% to 20% make little or no use. There scems to be practical unanimity also in the belief that if a better informed and more alert use of the available laboratory facilities could be achieved, either by education of the physician or by improving the quality of the laboratory service and the attitude of the laboratory men, one link in the chain of public health protection would be strengthened.

The Committee believes that practising physicians in the State fall into three categories: (1) Those who are familiar with laboratory proccdures and use available laboratory facilities promptly and intelligently. (2) A group of physicians who are more or less unfamiliar with laboratory examinations and their interpretation. These men often hesitate to make inquiries because of disinclination to display their ignorance. Many of them are anxious to learn more about the correlation of clinical medicine and labora-tory examinations. It appears that by properly devised measures of education this group might be helped a good deal. (3) A group of physicians who have no real interest in finding out more about a patient's condition or securing more

adequate checks on treatment. There is probably little that can be done to improve the work of these men and to create within them a public health attitude in their work.

It is the feeling of the Committee that the attitude of the laboratory man is in some instances partly responsible for the failure of the physician to make full use of laboratory facilities. If the laboratory man can create in the minds of physicians using his laboratory a feeling of confidence and an appreciation of the fact that the laboratory man wishes to aid the physician, without bringing out conspicuously his unfamiliarity with laboratory procedures, a mutually helpful relationship will exist. The attitude that the laboratory is always right has at times unquestionably alienated practising physicians and prevented them from being co-workers in the pullic health work of the State. It is realized that the achievement of a satisfactory relationship between the laboratory and the physician depends to a considerable extent upon the personality of the laboratory man.

Closely related to the attitude of the laboratory man in promoting effective use of laboratory facilities, is the quality of service rendered by the laboratory. Prompt and accurate reports and an unfailing attitude of courtesy are necessary in order to develop and maintain a satisfactory relationship between the laboratory and the practising physician.

RECOMMENDATIONS

The Committee recommends the following measures as designed to bring about improvement in public health laboratory service in the State:

- 1. Distribution from the local laboratories of brief accounts of laboratory procedures, each dealing with a single disease or a single procedure. It is proposed that these leaflets be prepared under the supervision of the Council of the Association and sold to local laboratories at a very low cost. They could be distributed from the local laboratories in any way the laboratory director considered advisable.
- 2. Unceasing efforts on the part of the laboratory director to send out prompt and accurate reports and to deal with physicians in a spirit of courtesy and cooperation.
- 3. Directors of laboratories should take the initiative in seeking opportunities to speak briefly before County Societies on some phase of laboratory diagnosis or correlation of laboratory work with clinical work. The Committee believes that such addresses should be short and frequent.

Furthermore, it is the belief of the Committee that attendance at County Society meetings by laboratory directors is important in order to

spread by casual contact at such meetings information regarding laboratory procedures.

4. It is considered important that speakers capable of discussing laboratory procedures and their interpretation be invited to speak before County Societies on topics having some relation to the use of laboratory procedures in medical and surgical diagnosis and public health work.

5. The Council of the New York State Association of Public Health Laboratories should encourage the presentation of papers at the Annual Meeting of the State Society, dealing with laboratory diagnosis and the effective use of the labora-

tory in public health work.

6. It is recommended that the Council of the Association cause to be published in a suitable medium short reports of instances in which the practising physician demonstrated intelligent and alert use of laboratory facilities, thereby making early diagnosis of a communicable disease and checking its spread. It is also recommended that instances illustrating failure on the part of the practising physician to use available facilities and thereby delaying diagnosis and the institution of measures to prevent spread of communicable disease, should be published in a suitable medium. In both cases, however, the reports should be made without mentioning names or localities.

It is suggested that laboratory directors who become familiar with conspicuous examples of intelligent use, or the reverse, of the laboratory by practising physicians, briefly report the facts in writing to the Council of the Association.

7. When it appears that a physician has shown himself unmindful of the regulations of the Sanitary Code regarding the submission of specimens from suspected cases of communicable disease to an approved laboratory, the laboratory director may with entire propriety remind the physician of his legal obligations under the Sanitary Code. He may also point out to him his precarious position in the event of a malpractice suit arising from a situation in which the physician has failed to comply with the regulations of the Sanitary Code.

8. The Committee considers it advisable to have from time to time as subjects for round table discussions at the annual and semi-annual meetings of the Association, topics related to the problem under consideration in this report.

9. As occasion arises, it is considered advisable to have laboratory directors add illuminating comments to the brief statements commonly comprising laboratory reports to practising physicians. When to do this and how to do it should be left largely to the discretion of the laboratory director.

Dr. V. W. BERGSTROM, Dr. A. W. WRIGHT, Dr. G. M. MACKENZIE.

MEDICAL CARE OF THE INDIGENT IN NASSAU COUNTY

The executive secretary of the Medical Society of the County of Nassau has distributed the following form of agreement which has been made by the Committee on Economics of the Medical Society of the County of Nassau with the Welfare Department of the County. This agreement is practically the same as that in force in the adjoining County of Suffolk.—Editor's Note.

Recognizing the seriousness of the problems and distress with which this county is faced, and desiring to insure the best possible medical care for those residents of the county who are unable to provide for themselves, the Medical Society of the County of Nassau and the welfare officers of the county mutually agree to the following general principles:

- 1. The medical care of the individual otherwise able to maintain himself is traditionally the responsibility of the medical profession, and the medical profession has no desire to be relieved of this responsibility. To that end the Medical Society agrees that the welfare departments should not be called upon to pay the ordinary medical bills of individuals who are not already listed as receiving aid from welfare organizations for the necessities of life other than medical care. It is recognized that exceptions might be made in cases requiring unusual procedures or prolonged treatment.
- 2. It is mutually agreed that in spite of the burdens of the present emergency, we cannot afford to cheapen the quality of personal service given the sick, and there should be no attempt at shirking responsibility by either the physicians or the welfare groups. Specifically, welfare officers will authorize treatment as far as is practicable by the traditional family physician, and the physician in turn shall render the best service possible, at the same time recognizing the financial difficulties involved in meeting unduly high bills.

3. To the end that these general ideals might be realized, the following suggestions are hereby adopted for the cooperation between the physician

and the public welfare officer:

 No physician shall render medical service to an indigent patient known to be a charge of the welfare department without previously receiving written authority from the proper welfare official, except in emergencies or when because of the hour such welfare officer cannot be reached or the necessary approval secured.

2. In the event of emergent treatment or in the event that treatment is rendered a patient found to be indigent and the responsibility of the welfare officer after the treatment is instituted, the physicians must notify the public welfare officer and request authorization within 48 hours of the first treatment for which pay is desired.

3. Authorization for medical care will not be given for a period of more than 4 weeks; at the end of which time the physician must secure a renewal of his authorization from the welfare officer. An exception to this ruling is made in the

case of the county welfare department which requests that special arrangement be made if treatment is to extend a period of one week. A statement covering professional services rendered to date must be submitted on the first of each month regardless of whether the treatment is to extend over into another month. It will not be possible to audit bills in which a change is made for services rendered during more than one calendar month.

- 4. To secure payment of his fees the physician must observe the following routine:
- a. A bill on the physician's own bill form must be sent to the welfare official as soon as the physician has finished treatment or at the end of each month if treatment is to be continued.
- b. Upon receipt of a bill for professional services which have been authorized, the welfare department which will make out a claim on the prescribed form, and return it to the physician who shall complete the information required, sign the claim before a notary public and return it to the welfare department.
- c. Information required to complete a claim shall include diagnosis or condition of patient, duration of treatment and nature of services rendered.
 - 5. Fees in general shall be as follows:

This fee shall include the prenatal examination, routine after care at the time of delivery and the customary post mortem calls, Unusual pre-natal care may be rendered when necessary provided authorization is received.

- Other fees for special services must be agreed upon between the physician and the welfare officer in each particular case.
- 7. A consultant shall not be called without authorization; a separate authorization shall be secured for each consultation.
- 8. In the event of a disagreement between the physician and the welfare officer over the amount of the bill, both disputants agree to place the matter before the committee composed of representatives of the medical society and representatives of the welfare departments other than the one concerned in the dispute. Both disputants agree to abide by the decision of such committee.

SARATOGA COUNTY

The annual meeting of the Saratoga County Medical Society was called to order at 3.45 p.m., October 27, 1932, in the Auditorium of the Metropolitan Life Insurance Company Sanatorium at Mt. McGregor, N. Y., William H. Ordway, M.D., presiding.

Drs. King, McElroy and Magovern, a committee to nominate officers, made the following nomina-

President, Dr. E. J. Callahan, Schuylerville. Vice-President, Dr. F. J. Sherman, Ballston

Secretary, Dr. H. L. Loop, Saratoga Springs. Treasurer, Dr. W. J. Maby, Mechanicville.

Censors, Dr. T. J. Goodfellow, Chairman, Saratoga Springs; Drs. M. J. McGovern, Saratoga Springs, and M. J. Cornthwaite, Ballston Spa.

Delegate to State Society, Dr. G. Scott Towne,

Saratoga Springs.

Alternate, Dr. J. R. McElroy, Jonesville.

These officers were elected unanimously.

A fee schedule for professional calls was discussed.

It was moved by Dr. King and seconded by Dr. McElroy, that a committee of three be appointed by the chair, to act as a membership committee for the purpose of securing new members and interviewing delinquent members. This was carried.

Dr. Callahan read the Kings County Medical Society Bulletin. Dr. Callahan moved that the President appoint a Committee on Publicity with Dr. Loop as chairman, to consider ways and means of publishing a bulletin of the Saratoga County Medical Society, at regular intervals, as a means of making known to the members of the Society information and news regarding medical legislation, Public Health matters, Welfare, etc. This was seconded by Dr. Maby and carried.

A motion was made by Dr. King and seconded by the President that a committee of three be ap-

pointed to attend to publicity on cancer.

The President read a letter from Dr. William P. Brown, who expressed the request that the Saratoga County Medical Society go on record as in favor of the tuberculin test on all school children, the consent of whose parents was obtained, this test to be followed in the positive cases by x-ray and other examinations.

Dr. Walton explained the operation of these tests in other counties, and made remarks about its value. Remarks were made by Dr. Oginsky, saying that the Society should find out about the dangers to the children from these tests. President said the danger would not have to be considered, because it was practically nil, and that the procedure would open up avenues leading to the discovery of infection in the parents, and that the danger resulting from not having these tests was more to be feared than having them.

Dr. G. Scott Towne moved that the Society go on record as favoring this procedure. It was seconded and carried.

Dr. J. S. Walton, District State Health Officer, explained the theory of the County Health De-

partment.

Dr. A. T. Davis, Health Commissioner of Suffolk County, described the operation of the Health Department of Suffolk County and the active support which it is receiving from the practicing physicians.

The following resolution, offered by Dr.

McElroy, was adopted:

Whereas: There have been several counties of the State operating under the present permissive Law, and a compulsory law of similar import has been receiving widespread attention and favorable consideration by many who are active in health work; and

Whereas: While we as physicians and members of the Medical Society of Saratoga County always have been, are, and will be, ready to approve of and adopt the best in medical progress, we are also citizens and taxpayers, mindful of the increased and sometimes burdensome taxation often following the administration of new activities, especially when governed by executives unacquainted with the habits, needs and desires of the residents in the localities over which they have control; and

Whereas: As active practitioners in the field. of both preventive and curative medicine, already giving freely of our time and talents for charitable purposes in its many guises, we are fully alive to the added burdens we might be called upon to bear under certain types of legislative enactment; therefore be it

Resolved: That the Medical Society of the County of Saratoga will and hereby does approve of a County Department of Health for this county, when, and only when, it contains the following basic provisions:

A. That such County Department of Health shall be the controlling authority over all public

health activities of the county.

B. That the Medical Society shall be recognized as the organization most necessary for the suc-

cessful fulfillment of any health program.

C. That the Executive of such County Department shall be a resident of New York State, licensed to practice in New York State, and with not less than ten years experience in the active practice of general medicine, preferably in the county in which they seek apointment.

D. That all existing Health Districts shall be represented by physicians acting as deputies to

the chief executive.

E. That whenever possible diagnostic clinics and all preventive and curative treatments shall be conducted by the physicians of the county.

A motion was made by Dr. King that the work

of the Commuttee on Resolutions on the deaths of Dr P M Bolton, Dr G F Comstock and Dr G F Fish be completed and spread on the mutures of the meeting This was seconded and carried

Dr Maby talked concerning the committeemen doing their work, etc., and suggested that the members who were appointed on committees and who could not serve so advise the President

A motion was made by Dr. Callahan that Dr. E. MacD. Stanton of Schenectady, and Dr. E. K.

Cravener of Schenectady, be sent a letter of thanks from the Society by the Secretary, for their fruitful endeavors in behalf of one of our members in his suit for mal-practice

After a social dinner a very interesting and enlightening address on "The Diagnosis and Treatment of Hypertension and Nephritis" was given by Dr Benjamin I Ashe of New York City This was very well attended there being present many physicians from all the neighboring counties.

ORANGE COUNTY

The 126th annual meeting of the Orange County Medical Society was held on December 13, 1932, in Mitchell Inn, Middletown, N Y, with fifty members present Officers for 1933 were elected as follows:

President, Dr. M. R. Bradner, Wai wick

Vice President, Dr. H. J. Shelley, Middletown Secretary-Freasurer, Dr. E. C. Waterbury, Newburgh

Censors, Dr W W Davis, Chester, Dr J A Noll, Port Jervis, Dr T D McMenamin, Highland Falls, Dr S W Mills, Middletown

Delegates to the State Society for 1933-1934,

Dr J B Hulett, Middletown

Alternates, Drs B McD Krug, Goshen, and

M E Osterhout, Cornwall

Four new members were elected, Drs James W Walton, Middletown, P H Faivre, Middletown, Harold T Werner, Cornwall, and T. R Proper Newhurgh

Dr Samuel W Mills, gave his address as re-

tiring president

The principal feature of the evening was the reception and discussion of a report on hospital charges for indigent cases which was submitted by a committee of which Dr W J Hicks, of Middletown, was churman This report, which was approved by the Society, was as follows

"I That in medical cases and non-operative surgical cases the charge for medical services shall be one dollar and a hilf per hospital day, irrespective of the number of daily visits

'2 That the charges for operative surgical

cases be fifty per cent of the prevailing charge for private patients, this charge to include aftertreatment while the patient is in the hospital

"3 That the surgeon's fee shall include that of

his assistant

"4 That the charge for anaesthesia shall be five dollars in cases under one hour of operation and seven and one half dollars in cases over one hour

"5 That a surgical fee of one hundred dollars shall be the maximum for any major operation, including the assistant's fee and aftertreatment

"6 That the charge for medical and surgical attention at an uncomplicated confinement case shall be twenty-five dollars and for an instrument

case thirty-five dollars

"7 We recommend that this schedule be worked out in greater detail during the next year and that conferences be arranged with the Economics committees of adjoining counties with a view to evolving a schedule of charges which will be uniform for the counties of Orange, Sullivan, Ulster, and Rockland"

The proposed schedule of rates does not affect home treatment in welfare cases. Of this the report notes "In most of the towns, however, the work is being done by the physicians of the locality on a fee basis in cooperation with the local welfare officers with varying degrees of satisfaction"

The committee favors that in welfare cases hospitals render a bill including both the hospital's ind the physician's charges

W J Hicks, Chairman

TIOGA COUNTY

The December meeting of the Tioga County Medical Society took place Tuesday evening, December 13, 1932 at the Green Lantern Inn, Owego N V with 25 members and gnests present The meeting was called to order at 8 00 P M following a steak dinner which was enjoyed by all, including our retiring president, Dr W A Moulton, who is recuperating from a recent choleocystectomy

The treasurer reported a balance of \$36.15

Drs A Knight of Waverly, and Harvey Klacr of Owego, were elected to membership

The subject of governmental paternalism and competition in including through the activities of Veterans' Hospitals was discussed. On motion the committee on Medical Economics was empowered to send letters to the names on the list suggested by the Committee of the State Society, in accordance with the advice of the State Committee on Medical Economics.

SARATOGA COUNTY

The annual meeting of the Saratoga County Medical Society was called to order at 3.45 p.m., October 27, 1932, in the Auditorium of the Metropolitan Life Insurance Company Sanatorium at Mt. McGregor, N. Y., William H. Ordway, M.D., presiding.

Drs. King, McElroy and Magovern, a committee to nominate officers, made the following nomina-

President, Dr. E. J. Callahan, Schuylerville. Vice-President, Dr. F. J. Sherman, Ballston

Secretary, Dr. H. L. Loop, Saratoga Springs. Treasurer, Dr. W. J. Maby, Mechanicville.

the chief executive.

E. That whenever possible diagnostic clinics and all preventive and curative treatments shall be conducted by the physicians of the county.

A motion was made by Dr. King that the work

WESTCHESTER COUNTY

The annual meeting of the Medical Society of the County of Westchester was held at Bloomingdale Hospital, White Plains, on the evening of November 15, 1932, with more than 125 members present. The following officers for the year 1932-33 were duly elected:

President, Dr. Andrew A. Eggston, Mount Vernon.

Vice-President, Dr. Mortinier W. Raynor, White Plains.

Second Vice-President, Dr. Theodore West, Portchester.

Secretary, Dr. Arthur F. Heyl, New Rochelle. Treasurer, Dr. Harry Klapper, White Plains.

Censors (two years), Dr. Louis B. Waldron, Yonkers; Dr. J. F. Black, White Plains; Dr. E. H. Huntington, Ossining.

Delegates (two years), Dr. E. W. Weber, White Plains; Dr. R. B. Hammond, White Plains: Dr. Arthur F. Heyl, New Rochelle.

Alternate Delegates (two years) Dr. F. E. Vaughan, Mount Kisco; Dr. Fred Brillinger, Peekskill; Dr. C. J. F. Parsons, Dobbs Ferry.

The following applicants were elected to full

membership:

Drs. Irving II. Beckwith, William G. Childress, J. Russell Foshay, Granville F. Knight, William E. Morris, M. W. Norton, and James Polsenski.

The chairmen of the various committees read and presented their reports which were distinctly informative of the various activities accomplished during the past year.

The report of the Public Relations Committee was given by its eliairman, Dr. C. C. Guion. (This report is printed on page 36 of this Jour-

nal.—Editor's note.)

Dr. W. W. Mott, Chairman of the Economics Committee, made his report and offered the following resolution, which was adopted:-

"The Medical Society of the County of Westchester, representing over five hundred (500) physicians practicing in Westchester County, State of New York, wishes to register an empliatic protest against the growing tendency of the Veterans Administration Hospitals to compete with the hundreds of approved hospitals now in existence and with the work of the individual practitioners of medicine. As a matter of economy, the enormous expense involved in building and maintaining government hospitals is one of the many menaces to our economic security, especially when it is a fact that with proper organization every Veteran who is entitled to medical care at the expense of the government could be treated with the same efficiency and skill by the independent practitioners in his home community, and in the many approved hospitals that could at all times furnish adequate accommodations. We further demand the clinination of the growing expenditure of the Federal Government, already in excess of \$450,000,000, per annum for benefits of Veterans of the Spanish and World Wars who suffered no disability in fact through 'War Service.' "

The retiring President, Dr. Louis V. Waldron, and the incoming President, gave addresses, outlining the past and future work of the Society.

Dr. Charles A. Elsberg of New York gave a most worthwhile paper on "Some Facts Concerning Tumors of the Brain and Spinal Cord," illustrated with lantern slides. The paper was dis-cussed by Dr. Joseph E. J. King, Dr. Edwin G. Ramsdell, Dr. Mortimer W. Raynor and Dr. George W. Henry.

Following adjournment, an execllent collation was served.

ARTHUR F. HEYL, M.D., Secretary.

RENSSELAER COUNTY

The annual dinner meeting of the Rensselaer County Medical Society was held in the Troy Health Center, on the evening of December 13. The principal business was the election of officers for the year 1933. The following were chosen:-

President: Dr. Warren W. St. John, Troy. Vice-President: Dr. Walter H. McShane, Troy. Secretary: Dr. Clement J. Handron, Troy. Treasurer: Dr. John F. Russell, Troy.

Censors: Dr. C. W. Hamm, and Dr. T. F.

Judge.

Delegates to State Society: Dr. A. J. Hambrook and Dr. John H. Reid.

Alternates to State Society: Dr. J. J. Quinlan and Dr. F. W. Caird.

A new office, that of President-Emeritus, was created and Dr. O. F. Kinlock, who has been practicing for 53 years, was elected to fill it.

The Society reconvened on the following evcning at the Hendrick Hudson for its annual bauquet. The after-dinner program was scientific in character, as follows:

"The Surgical Consideration of Jaundice," by Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York.

"Arthritis" by Dr. Ralph Pemberton, of the School of Medicine of the University of Pennsylvania.

W. B. D. VAN AUKEN, Secretary.

Officers for 1933 were elected as follows: President, F. A. Carpenter, Waverly. Vice-President, A. C. Hartnagle, Berkshire. Secretary-Treasurer, I. N. Peterson, Owego.

Delegate, G. S. Carpenter, Waverly. Alternate, W. A. Moulton, Candor.

Censors, W. A. Moulton, Candor; E. S. Beck,

Owego: F. H. Spencer, Waverly.

Dr. F. A. Carpenter read the committees appointed for 1933 and asked their cooperation and prompt attention to the matters referred to them.

Dr. G. S. Carpenter introduced discussion of a Post-Graduate course of lectures for 1933. On motion the Committee on Medical Education was empowered to select and arrange for such a course to be held in 1933.

The secretary read a communication from the

State Committee on Public Relations which defined the aims and objects for 1933.

Dr. W. H. Ross, secretary of the State Committee on Public Relations, was introduced and spoke in an interesting and enlightening manner on the work of the Committee on Public Relations and the part of the county societies in the changing aspects of medical practice.

Dr. Harry Fish of Sayre, Pa., assisted by B. F. Cary of the Tioga County General Hospital, gave an interesting discussion of "The Diagnostic Value of the X-Ray." He stressed its value as an adjunct to diagnostic measures after the histery and physical examination of the patient was completed. A representative number of rontgenograms were presented.

The meeting was adjourned at 10:30 P.M.

IVAN N. PETERSON, Secretary.

HERKIMER COUNTY

A meeting of the Herkimer County Medical Society was held in Herkimer on October 11, 1932. The notices of the meeting carried the announcement that a popular meeting and dinner would be held on the afternoon and early evening of the same day in order to popularize the movement for the control of venereal diseases. The popular meeting was addressed by men prominent in public health work.

Dr. James W. Graves, Health Officer of Herkimer, presided, and explained the objects of the meeting.

Dr. George S. Eveleth, the Health Officer of Little Falls, explained the State Law relating to the control of the diseases.

Dr. Alfred Pfeiffer of the State Department of Health, outlined the educational program of the State Department of Health, and the influence of playgrounds and recreational facilities in the control of venereal diseases.

Dr. J. N. Vander Veer, Liaison Officer of the State Medical Society, outlined a plan for the participation of the County in the control of venereal diseases.

Dr. Halsey J. Ball, District State Health Offi-

cer, outlined the measures which would be practical in Herkimer County.

The speakers also spoke on the same topics before the Exchange Club, a business club of the City of Herkimer.

The Herkimer County Medical Society met in the evening and transacted routine business.

The 126th annual meeting of the Herkimer County Medical Society was held with a dinner meeting on the evening of Tuesday, December 13th. Election of officers for the ensuing year The retiring President, Dr. T. B. was held. O'Neil, gave an address going over the activities of the Society for the past year.

Dr. O. H. Love, the newly elected President, appointed the standing committees for 1933.

The Society discussed the report of the Committee on the Costs of Medical Care and supported the minority report.

Because of physical disabilities which have forced him to retire from practice after thirty years as an active member of the Society, Dr. George H. Smith of Little Falls was made an honorary member of the Society.

Fred C. Sabin, Reporter.

SULLIVAN COUNTY

A special meeting of the Sullivan County Medical Society was held at the Elks' Club, Monticello, on the evening of November 24, with 28 county physicians present-a large attendance. Dr. J. M. Rosenthal, president of the Society, presided.

Dr. William H. Ross, of Brentwood, L. I., expresident of the New York State Medical Society. spoke on what the public expects of the doctor today in preventive medicine, and described the health department of Suffolk County.

Dr. Frank G. Laidlaw, of Middletown, deputy

state health commissioner, discussed Dr. Ross' paper at length.

Dr. Irving J. Sands, of Brooklyn, visiting neurologist at the Neurological Institute and associate in neurology at Columbia University, spoke on "Cerebral Vascular Disorders." The paper was of vital interest because of the prevalence of these disorders. His talk was accompanied by lantern slides, and was followed by a long discussion.

HARRY GOLEMBE, Chairman, Publicity Committee.

WESTCHESTER COUNTY

The annual meeting of the Medical Society of the County of Westeliester was held at Bloomingdale Hospital, White Plains, on the evening of November 15, 1932, with more than 125 members present. The following officers for the year 1932-33 were duly elected:

President, Dr. Andrew A. Eggston, Mount Vernon.

Vice-President, Dr. Mortimer W. Raynor, White Plains.

Second Vice-President, Dr. Theodore West, Portchester.

Secretary, Dr. Arthur F. Heyl, New Rochelle. Treasurer, Dr. Harry Klapper, White Plains.

Censors (two years), Dr. Louis B. Waldron, Yonkers; Dr. J. F. Black, White Plains; Dr. E. H. Huntington, Ossining.

Delegates (two years), Dr. E. W. Weber, White Plains; Dr. R. B. Hammond, White Plains; Dr. Arthur F. Heyl, New Rochelle.

Alternate Delegates (two years) Dr. F. E. Vaughan, Mount Kisco; Dr. Fred Brillinger, Peckskill; Dr. C. J. F. Parsons, Dobbs Ferry.

The following applicants were elected to full

membership:

Drs, Irving H. Beckwith, William G. Childress, J. Russell Foshay, Granville F. Knight, William E. Morris, M. W. Norton, and James Polsenski.

The chairmen of the various committees read and presented their reports which were distinctly informative of the various activities accomplished during the past year.

The report of the Public Relations Committee was given by its chairman, Dr. C. C. Guion. (This report is printed on page 36 of this Jour-

nal.—Editor's note.)

Dr. W. W. Mott, Chairman of the Economics Committee, made his report and offered the following resolution, which was adopted:--

"The Medical Society of the County of Westchester, representing over five hundred (500) physicians practicing in Westchester County. HARRY GOLEMBE, Chairman, Publicity Committee.

TESTS OF LIFE

Whether a person is alive or dead at a certain time may be of great legal importance. Discussing the tests of life the New York Herald Tribune of December 12 says editorially:

"Perhaps no single observation in the history of biology has had so much effect on human thinking as the prehistoric identification of life with its most visible sign, the breath. Here began the Greek doctrine of the psyche; that imagined immaterial something which went in or out with breath and whose departure was assumed to mean life's end. To this, plus the fact that individuals may cease to breathe for a time and yet recover, may be traced most of human thoughts about spirits, immaterial beings and the soul. The Egyptians had a different idea, accepting as life's essential seat and center the beating heart and other organs of the trunk-ideas which still survive in such faded metaphors as 'heartsick' or the phrase that one 'has no stomach' for a task. It is curious, however, that the oldest Egyptian biological document which survives, the Edwin Smith papyrus, recognizes the controlling influence of the brain rather than the heart, but this seems to have been a bit of surgical knowledge which never spread to the philosophers

"Modern science is not much better off in defining life than were these ancients who hesitated between heart, brain and breath as being its essence. No one dies all at once, Breathing stops for a but only piece-meal. time, or the circulation of the blood. Probably the first organ, then, to succumb permanently is the brain. Others, including the heart muscle, may live for hours, or even days, in the sense that the protoplasmic cells of these organs still live and could grow if removed. To say precisely at what instant a person dies seems to be impossible, however much the law courts may demand to know. So it is impossible to say for certain whether a person in the midst of dying is already dead or still alive."

RURAL PHYSICIANS

The following editorial in the New York Sun of December 21, 1932, closes with a novel reason why rural towns fail to advertise for a doctor:

"What can be done to lure doctors out of the cities into the small towns, suburbs and villages? If the seriousness of this problem can be measured by the number of persons who view it with alarm, then it appears to be the hardest nut the medical profession must crack. Dean Rappleye, of Columbia University's School of Medicine, is the latest to deplore the urban preferences of physicians. In his annual report he shakes his head over the crowding of the profession into sections where a surplus of doctors already exists; too many of the nation's 156,000 doctors practice in large cities. He attributes the concentration to the

desire for easier incomes, better educational opportunities and more attractive social life than suburban or rural sections can offer.

"But what can be done about it? What agency has the right to assume the duty of telling doctors where they shall practice? Suppose there are hundreds of towns that need another doctor, how can that fact be made known? Maybe there is a luerative practice in any one of a score of upstate villages if only some enterprising physician will go after it. But a town cannot very well advertise its need for doctors. It would not look well for the chamber of commerce of Blunkityville to announce that the town can keep five more doctors busy; on the contrary, the tendency is to tell the world that a town is so healthful that only the doctor goes hungry.

SCIENCE IN THE NEWS

The New York Times of November ninth called editorial attention to the intrinsic value of news of a scientific value as compared with the mere epheneral interest in the sensational columns. The Times probably includes medical news when it says:

"Science in the weekday edition of the New York Times for the year 1928 averaged daily a column length of 32.42 inches, or about one and a half of our regular columns. This is the report of a survey made at the University of Kansas.

"Before we hasten to draw invidious compari-

sons between one and a half columns a day for the progress of science, and scores of columns for politics or sports or "crime news." it would he well to take into account what might be called the relative specific gravity or nutritive value or alcoholic content of the different classes of news. It is perfectly plain that a column of scientific news makes many more times the demand upon the reader's assimilative powers than a column of Congressional oratory or gangster warfare.
"A column and a bat of delive scientific above."

"A column and a half of daily scientific chronicle, provided it is authentic and undiluted,

should contain a lot of popular education."

BOOKS RECEIVED

- Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.
- DISEASES OF THE SPINAL CORD. By WILLIAMS B. CABWALADER, M.D. Octavo of 204 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1932. Cloth, \$5.00.

- A MANUAL OF EMBRYOLOGY. By J. ERNEST FRAZER, F.R.C.S., Eng. Octavo of 486 pages, illustrated. Baltimore, Williams & Wilkins Company, (William Wood & Company), 1932. Cloth, \$8.00.
- THE EARLY DIAGNOSIS OF THE ACUTE ABBOMEN. By ZACHARY COPE, M.D. Sixth Edition. Octavo of 248 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$3.25. (Oxford Medical Publications.)
- STREPTOCOCCI IN RELATION TO MAN IN HEALTH AND DISEASE. By ANNA W. WILLIAMS, M.D. Octavo of 260 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$5.00.
- Poliomyelitis. A survey made possible by a grant from the International Committee for the Study of Infantile Paralysis. Octavo of 562 pages, illustrated. Baltimore, Williams & Wilkins Company 1932. Cloth, \$6.00.

BOOK REVIEWS

AN Introduction to Dermatology. By Richard L. Sutton, M.D., and Richard L. Sutton, Jr., M.D. Octavo of 565 pages, illustrated. St. Louis, Mo., C. V. Mosby Company, 1932, Cloth, \$5.00.

This volume is an abridgement of an excellent reference book on diseases of the skin, in which R. L. Sutton, Jr., not only deletes with unusual care material from Sutton's eighth edition of "Diseases of the Skin," which he does not consider essential for text-book purposes, but also includes résumés or makes mention of recently published articles on pituitary extract injection in alopecia, bismuth therapy in the treatment of lupus erythematosus, baeteriophagia, crude tar treatment of

The book is well written, concise, and sufficiently illustrated to make it an invaluable text-book for the ARTHUR M. PERSKY. student.

PRACTICAL TREATMENT OF SKIN DISEASES. By EBUARD AHLSWEDE, M.D. Octavo of 770 pages, illustrated. New York, Paul B. Hocher, Inc., 1932. Cloth, \$12.00.

This text is a departure from the usual one on Dermatology in that it is devoted to therapeuties. One would not use it for the purpose of finding a word picture of a skin disease, or being able to make a differential diagnosis between two similar diseases, but, after having made the diagnosis he would use this book for detailed, and accurate, description of the application of his thera-peutic measures. This fact applies particularly to the physical procedures.

There is also a large part of the text devoted to the drugs used in dermatological therapy, and many prescriptions containing them, but one notices the great pre-dominance of drugs used mainly in Europe. There are, liowever, many prescriptions containing drugs very com-monly used in this country.

The reviewer believes that this book will be of greatest value to the practitioner who has not had special derma-tological training, and is, therefore, unfamiliar with the

The arrangement of the text is very good, and the author has shown great care in the selection of his material. The publishers have also contributed considerably in the production of a book in which the desired information may be readily found.

Much of the therapy that is distinctly European is of value to the dermatologist of this country as well as to the general practitioner. E. ALMORE GAUVAIN.

Individuality of the Blood in Biology and in Clinical and Forensic Medicine. By Leone Lattes. Octavo of 413 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$7.50.

This book, which was first published in Italian in 1923, which was then translated into German and enlarged by Schiff in 1926, and which was revised and published in French in 1929, has been brought up to date and is now published for the first time in the English language, Data on the heredity of the Landsteiner blood groups totalling extensive hibliography is given at the end of the book,

ALEXANDER S. WIENER.

PHYSICAL THERAPEUTIC TECHNIC. By FRANK BUTLER GRANGER, M.D. Second edition, revised by WILLIAM D. McFee, M.D. Octavo of 430 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth,

The book is good, replete with information which is of value to all medical men. In the preface, the author claims, "it is not to be a book for the specialist in Physical Therapy," but even they will enjoy reading its well written matter, and may oftentimes avail of it as a ready reference book. To the Physician who dispenses Physi-cal Therapy a little but not en irely it is almost a necessity with its easily found and well informing facts. To the other specialties and to the general practioners who do not use or know little of Physical Therapy it should be indispensable to have at their finger tips a volume which is so abreast of the advances in this particular branch of Medicine.

There are many diverging opinions upon some of the matter contained. Any frequent user of the Physical Therapy modalities may disagree entirely with some of the statements made by the author and its revisor. In some particular instances, the reviewer finds poor re-sults attained by some of the methods advised and good sants attained by methods condemned. Technique is largely a matter of guide-posts, one man's teelinique may be another man's folly. Every Surgeon is not capable in all branches of Surgery, neither is every man capable in all types of Clinical Physical Therapy. Condemnations of Surgery and Surgery an tion of technique should not be done unless results are not fortheoming.

John J. Hauff.

Manic-Depressive Psychosis. An Investigation of the Most Recent Advances. The Proceedings of the Association New York, December 29th and 30th, 1930. Editorial Board, William A. White, M.D. and others. Octavo of 851 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, \$10.00, (Association for Research in Nervous and Mental Disease. Vol. XI of a Series of Research Publications)

Essentially a compilation of authoritative data by numerous invastinger calcing to the city of manic depressive depresive depressive depressive depressive depressive depressive depres particular subject. This book is no exception.

Each previous book has been enhanced in value by a thorough summary of the literature. In the historical review of the manie depressive reactions we find Smith Ely Jelliffe at his best.

Some conception of the scope and all around attractiveness of this work can be best gained by a listing of the subjects discussed.—Historical, Constitutional (organicbody build), Affective psychoses in children, Etiology (Psychogenic factors) Mechanisms, Symptomatology, Psychology, Prognosis, Biology, Statistical, Treatment, Ethnology (Manie depressive reactions in Negroes).

The section of Symptomatology is complete, including chapters, to mention a few, on the blood-cerebro-spinal fluid, acid base equilibrium of the blood, effect of emotion of gastric secretion, basal metabolism, gastrointestinal motor function in manic depressive psychoses, behaviour chart, statistical delusional study.

A collaborative attempt is rarely complete. However, all of the essentials, pertinent to this subject, are so presented that this book should be well received,

HAROLD R. MERWARTH.

CANDIDATES' MEDICAL PLATFORM IN WEST VIRGINIA

The November issue of the West Virginia Medical Journal contains the following editorial on the medical platforms of the candidates for Governor of the State:

"An editorial under the caption, 'Medical Supervision,' was published in the October issue of this Journal dealing with alleged conditions of neglect in many of the state institutions caring for the sick. It was pointed out that the cause of this alleged neglect was due to a lack of proper medical supervision over the institutions themselves. The editorial proposed that a medical board of governors or supervisors be appointed by the Government from an approved list submitted by the Association to have complete medical supervision over all state institutions dealing with medical care.

"We are pleased to announce that both the Republican and Democratic candidates for Governor, Mr. Townsend and Judge Kump, have declared themselves in favor of the remedy suggested by the Journal. With these declarations, we feel that we have successfully crossed an important milestone in our efforts to secure better care and attention for the state's wards.

"In publishing the statements of Mr. Townsend and Judge Kump, we first wish to extend to each of these distinguished statesmen our appreciation of the confidence and faith in which they hold the medical profession of West Virginia. We feel that no further comment is necessary.

"Judge Kump has written us as follows:

"'My attention has been called to the editorial under the caption "Medical Supervision"

in the October, 1932, number of the West Virginia Medical Journal. I am in accord with the spirit of the editorial and so expressed myself when I was not a candidate for office. The care of those sick in body or mind should be entrusted to people fitted by talent, training, experience, and sympathetic understanding, for this essential and humane service. They should not be forced to submit themselves to politicians and political henchmen.

"Mr. Townsend's statement reads:

"I have read with a great deal of interest the editorial in the last number of the Medical Journal suggesting that the medical fraternity of the State be more freely consulted by the chief executive in the matter of the conduct of those state institutions charged with the responsibility of caring for unfortunates who are afflicted in body and mind.

"I am in hearty accord with this suggestion. If I am elected Governor of West Virginia, I shall not only welcome but will seek the advice and counsel of the duly chosen representatives of the physicians of the state in the matter of selecting the superintendents of such institutions, and also in all matters of

policy affecting these institutions.

"The problem of caring for the state's unfortunates is one that transcends politics. It should be treated as the humanitarian question that it is. Obviously the only group qualified by training and experience to give assistance to the governor in such matters is the medical fraternity, and it is to that fraternity that I would expect to turn. With their help I believe it is possible to work out a program that will insure intelligent and effective care of our unfortunates."

LEAGUE OF CHRISTIAN PHYSICIANS OF KENTUCKY

The November issue of the Kentucky Medical Journal contains the following description of a religious service held just before the annual meeting:

"The League of Christian Physicians of the Kentucky State Medical Association held their meeting at the Warren Memorial Church Sunday, preceding the general session, Doctor Howard A. Kelly, Baltimore, the distinguished surgeon, naturalist, and writer, was the speaker. Many of the churches of Louisville united

with the League. The large auditorium which seats nearly 3,000 people, was filled and extra chairs had to be provided for the large crowd."

We received the following letter from Dr. Lillian H. South, describing the League and the meeting:

"The League of Christian Physicians of the Kentucky State Medical Association is composed of doctors who take an active part in church work and on Sundays preceding the

4 New Concentrated Vitamin Products

Vitamin A alone

Name SmacoCaritol Product No. 505

Description: Catitol is a 0 3% solution of carotene in bland oil, providing a safe, palatable and convenient concentration of vitamin A for therapeutic use

Taste: Intire absence of all fishy taste makes it accept able to your patients

Color: Deep sed, due to carotene.

Potenty Ten drops contain one thousand International Units of vitamin A

Dosage: Three to five drops daily for infants and young children Five to ten drops daily for adults

Package: 15c c dropper top, protectively-colored botiles, in special cattons to shield it from the light

Cost. Because of its high po rency and the small doses required, it is an inexpen sive source of vitamin A, in spite of the fact that it is the only product contain ing vitamin A alone

Indications: For conditions caused by vitamin A defi ciency and cured or pre vented by adequate vitamin A or carorene dosage

Vitamin D alone

Name: Smaco Concentrated Vitamin D Product No 515

Description: This product is Natural Vitamin D, being a highly potent extract of the antimelitic principle of cod liver oil

Taste Palatable and free from objectionable taste

Color: Nearly colotless.

Potency. Ten drops are equal in vitamin D potency to threeteaspoons of standard potent cod liver oil

Dosage: Average prophylac tic dose, ten drops daily Average curative dose, fif teen to thirty drops daily, depending on severity of case.

Package Sc.e and Soc.e pro tectively colored bottles

Cost: Approximately the same as that current for equivalent vitamin D dos ages of plain cod livet oil.

Indications. For the preven tion or cure of rickets and spasmophilia, and where-ever vitamin D therapy is required, such as tetany and osteomalacia

together

Name: Smaco Vitamins Aand D Product No 525.

Description: Smaco Cantol and Smaco Concentrated Vitamin D are combined in this product, providing both vitamins A and D in concentrated form for therapeutic use

Taste: Palatable and free from objectionable taste

Color: Red, due to carotene.

Potency Ten drops are equivalent to one thousand International Units of vita min A plus the vitamin D potency of three teaspoons of standard potent cod liver oil

Dosage: Ten drops or more daily, depending upon in dividual requirements

Parkage. Sc c and 50c.c pro tectively-colored bottles

Cost: Approximately the same as current prices for equal dosages of other vitamin concentrates

Indications: Wherever vitamins A and D are required together in palatable form and small dosage

Vitamins A and D Smaco Cod Liver Oil fortified

Name: *Smaco Cod Liver Oil (with Carotene and Con centrated Vitamin D) Prod uct No 510

Description: A high gradecod liver oil fornfied with vitamin A of vegetable origin (carotene) and natural vitamin D described in the second column.

Taste: Although carotene is not a flavoring agent, nevertheless the addition of carotene noticeably im proves the flavor

Color: Deep red, due to carotene it contains

Potency. One teaspoon is equivalent in vitamin D potency to three teaspoons of standard potent cod liver oil plus 1,000 Inter-national Units of vitamin A per teaspoon in addition to the original vitamin A potency of the oil

Dosage: One teaspoon daily for average individual needing vitamins A and D

Parkage: Tour ounce protectively-colored bottles packaged in special cartons to shield from light

Cost. Approximately one half as much as the equivalent amounts of vitamins A and D when purchased as plain cod liver oil 1

Indications Whereveramote palatable, concentrated cod liver oil is indicated (Only one-third as much is re quired as plain cod liver oil)

* This product is the Smaco Cod Liver Oil with Carotene announced in September, further improved by the addition of the new Columbia Zucker natural vitamin D

New Vitamin Therapy Possible

٥

Up to this time it has not been possible to prescribe visinin A alone, as in cases where vision D is not required or is already supplied by sunshine, ultra violet light, viosetool, etc. Smaco Cattof make possible the administration of Primary Vitamia A in drop doses, thus permitting the physician to regulate the dosage to meet individual tequirements

Smaco Vitamin D is natural vitamin D It is not an irradiated oil and not a cod liver oil concentrate, but tathet a highly porent extract of the antifactitic principle of cod livet oil. It is produced for therapeutic use by methods (Zucker Process) developed in the department of Pathology of the College of Physicians and Surgeons of Columbia University

BUDGETED MEDICAL SERVICE IN NEBRASKA

The following plan for group medical service at a fixed rate per year is described in the Nobraska State Medical Journal for October; but it has not yet developed beyond the stage of theory:

"Budgeted medical service was considered in Omaha last month, but was rejected by the Omaha-Douglas County Medical Society.

"The proposal is that the medical society, hospitals and nurses offer the services of all general practitioners, specialists, surgeons and others for any medical or surgical service whatever for a flat price of 3 per cent of the family income.

"According to the proposal, this 'budgeted medical service' would be limited to families whose income is \$2,700 a year or less. It would not be offered to those of higher salaries or income.

"The 'health policies' so offered to families would be cancellable only because of deceit or fraud. The size of the family would make no difference in the fee.

"Unemployed would be carried for three months as delinquent.

"Any person who was sick and was a member of the society's health budget plan would choose his own doctor, nurse and hospital.

"The medical side of the matter would be controlled by an executive committee chosen by the

medical society.

"The financial end would be handled by the originator of the plan, who believes 10,000 members can be solicited for the plan in two years.

"Each physician or surgeon would be required to list a regular schedule of fees for patients in the \$2,700-and-under class.

"Each month's receipts under the plan would be pooled and the total of all physicians', nurses' and hospitals' bills chargeable to the plan likewise would be pooled.

"If the bills in any one month totaled \$15,000 and the income for the month was \$10,000 payment would be made to the individual doctor on the basis of two-thirds of his bill. The next month would start with a clean slate.

"One must admit that the plan is unique, whatever drawbacks might develop in its application to actual conditions."

THE RESERVE THE PROPERTY OF THE PERSON NAMED IN

TRAINING SCHOOL SURGICAL FITTERS

February 6th to 10th, 1933, inclusive

This practical training course conducted by S. H. Camp and Company during the last three years in five principal cities of the United States and London, England, is designed to prepare fitters to cooperate with physicians more effectively by meeting actual conditions encountered in store fittings more intelligently and scientifically. It has been accorded the interest, cooperation and endorsement of leading physicians, representative surgical houses, and better drug

stores and department stores dispensing surgical garments. The program includes lectures and discussions on practical technique of surgical fitting, elementary anatomy and physiology, illustrated by charts, motion pictures and living models, with demonstrations on actual patients, under the supervision of Ariel Nichols Le May, Educational Director, and Dr. Rhoda Grace Hendrick, Medical Director, assisted by a corps of instructors.

PHYSICIANS! YOU ARE INVITED

For hetter service in assisting you with your surgical fittings, by the surgical houses, drug stores and other stores, dispensing the surgical garments you prescribe for your patients, you are invited to attend and participate.

The Natural Source

ALYCIN is supplied in 4-pound and 1-pound bottles

MAN in his ingenuity makes imitations of natural products—the pearl for example—but here as elsewhere there is a quality about the natural product which defies artificial duplication.

Similarly in the therapeutic field, chemists have made many synthetic imitations of the natural product—for instance, salicylates, But physicians continue to prescribe Merrell's Natural Salicylates, because they desire the maximum in therapeutic effect with the minimum disturbance.

ALYCIN

NATURAL SALICYLATES WITH AN ALKALI

Following the trend of current medical opinion, the House of Merrell has developed another form of salicylate medication—Alycin. Alycin combines natural salicylates with a balanced alkaline formula. Authorities emphasize the advantages of this combined form of treatment in colds, influenza, rheumatism, arthritis and similar conditions.

ALYCIN IN COLDS

The association of a balanced alkali with the salicylates in Alycin, combats the tendency to acidosis, favors recovery, and helps prevent complications.

A level teaspoonful of Alycin presents a mixture of 10 grains combined natural salicylates in an alkaline base, 20 grains.

PUBLICATION RULES IN COLORADO

The November number of Colorado Medicine contains the following announcements regarding its publication of articles:

"Hereafter eight published pages (approximately 4,800 words without cuts) will be the positive limit of length for original articles unless the author wishes to reimburse the journal for the cost of preparing additional

"Under previous rulings and custom, authors paid half the cost of all cuts published with their articles, the journal paying the remainder, except that the journal carried the full cost of cuts used with papers by the invited guests of the Annual Session. This is now changed as follows: An author will not be charged for the first five dollars worth of cuts used with his articles; he will be charged 50 per cent of the next ten dollars worth of cuts, and will be charged the full amount of all cost of cuts above fifteen dollars.

"Hereafter all books received by Colorado Medicine for review will be retained in the jurisdiction of the editorial department under the direction of the Scientific Editor until reviews of them have been received, at which time they will be turned over to the Library of the Medical Society of the City and County of Denver for custody. The Scientific Editor will assign all such books to reviewers.

"Hereafter all discussion of Annual Session papers will be published in abstract. Discussers will be provided with a transcript of their remarks so that they may themselves abstract them if they so prefer, subject to final abstracting and editing by the Scientific Editor."

BARBERS' CERTIFICATES IN KENTUCKY

The September issue of the Kentucky Medical Journal calls attention editorially to a new law in Kentucky requiring every barber and "beautician" to have a certificate from a physician that the operator is free from communicable disease. The striking feature of the article is that it calls attention to the fact that a doctor who gives the certificate lays himself liable to a suit for personal damages instituted by any person who may be infected by the operator. The editorial is as follows:

"Under the new law requiring registration of barbers and beauticians, a certificate from a registered physician is required that the applicant is free from contagious and communicable diseases. In this requirement is found probably ninety per cent of the value of this law. The

(Continued from page 56-adv. xx)

manner in which these examinations are made will determine the value of the certificates ımder it.

"Each applicant should be given a general physical examination and should be especially examined for skin diseases, including those of the scalp. No certificates should be issued without procuring a negative Wassermann. Examinations for gonorrhea should include microscopic smears. Of course, every physician will realize his responsibility under this law. Our attorneys advise us that there is no question but that a physician, in giving a certificate of freedom from contagious and communicable diseases to an applicant that he has not carefully examined, would be liable in personal damages, by any person infected by such a barber or beautician.

"This matter of certification is not only of importance in the barbers' and beauticians' law.

but is of general importance. A certificate of freedom from disease should never be given to anybody without the careful examination that will enable the responsible physician to really be as sure of his facts as modern science makes possible."

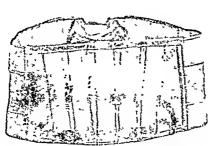

MEDICAL ECONOMICS IN WYOMING

The Wyoming section of the July number of Colorado Medicine contains an editorial suggestion for consolidating the several State Boards of professional examinations in the interest of economy. The writer says:

"Today we are all poor. There are no rich people left. There used to be a few in Wyoming, but not so today. Wyoming as a state is rich in natural resources, but ready cash is as 'scarce as hen's teeth'.

"Several thousands of dollars can be saved by consolidating all the examining boards in the state and at the same time just as good results can be secured. The Medical, Dental, Nursing, Pharmacy, Chiropractic, Optical, Law, Engineers, Mortuary, etc., boards could be consolidated as one examining board and save several thousand dollars a year. A secret committee from the different State Societies could prepare the questions, and the examining board could hold two examinations each year and do all the work now done by nine or ten boards.

"Cost of government must come down to meet (Continued on page 58-adv. xxii)

(Continued from page 57-adv. xxi)

the times, and the man who tells you prosperity is just around the corner is nowhere to be found. Hard work, and lots of it, is ahead for several years and we might just as well face the music. In August. 1931, we advocated an open cut in the fees charged for surgical services, in place of cutting them behind each other's backs. Today conditions have changed.

"Men whose investments in stocks and bonds used to bring in their owners good dividends, receive little or nothing and many of the stocks are not worth ten cents on the dollar. Look at the depreciation in all property and losses in valuation and then try to find any reason for nine or ten examining boards. Let the medical profession take the lead in offering such a consolidation and show our willingness to meet the conditions of today.

"Each State Society could select and recommend for appointment to the governor three men in Cheyenne or near Cheyenne to serve on this Consolidated Board so that traveling expenses could be cut out and the job just as well done, perhaps better than under the old system. This would result in non-partisan boards and would

eliminate party politics."

JOURNAL OF OKLAHOMA

The editor of the Journal of the Oklahoma State Medical Association makes the following appeal to the members in the October issue of the Journal:

"And read from cover to cover. You will note that many advertisers change their copy monthly and have something worthwhile in the way of a message for the physician.

"We have a suspicion that a certain per cent of our members do not read their Medical Journals, unless they happen to be especially interested in some one or more particular articles. This is a mistake, for our writers nearly always make an attempt to so frame their articles that they will appeal to the general practitioner; and this is the correct attitude for the mass of Oklahoma physicians do general work and are not specialists.

"In the back end of the Journal is a directory, containing the list of officers, delegates to the American Medical Association and members of various committees. Notwithstanding this we constantly receive letters wanting information which that page carries monthly. This is rather proof positive to us that some of our members do not read their

Journal,

"It may interest our readers to know that articles published in the Journal of the Oklahoma State Medical Association are rather widely abstracted. One of the most scientific

publications in the United States finds the articles meritorious enough to abstract several
each year.

"Our abstracts are very carefully selected and some of them are unusually worth while. The members who fail to read the Journal will overlook something worth while to himself."

WOMEN'S CLUBS AND HEALTH IN ILLINOIS

The Illinois Medical Journal for September prints the following after of the Federation of Women's Clubs made to the Education Committee of the Illinois State Medical Society to cooperate with the niedical profession in public health work:

"As State Chairman of Public Health, Child Hygiene, and Mental Hygiene of the Illinois Federation of Women's Clubs, I should like to place before you my proposed working program.

"As you may know, I have a District Chairman in each of the Congressional districts of the State. It is my plan to have each District Chairman, or her representative, seek a conference with a designated member of each County Medical Society.

"I should like to be able to give each of my chairmen the name of a pivotal representative of the Medical Society in each county, to whom she may go for consultation and guidance in health projects best suited to the needs of the community. In such projects I earnestly hope for medical leadership.

"I am asking each chairman to ascertain for me what, in her opinion, seems to be the health need of the various counties in her district. In the meantime you might wish to secure similar information from the County Medical groups, and these data can then be correlated.

"I feel that the physicians will benefit by thus inaugurating the health work in their communities, and the club women will profit by the expert counsel they will receive.

"Hoping that we will have this work well under way in the early fall, I am

"Very cordially yours,
"(Signed) LENA K. SADLER."

DR. EMMA T. MILLER, TEXAS

The November issue of the Texas State Journal of Medicine notes the death of Dr. Emma T. Miller, of San Antonio, aged 67 years, whose life was so original as to be worthy of notice. Doctor Miller spent the first seventeen years of her medical practice as a medical missionary among the women and children of Tabriz, Persia.

She was compelled to leave Persia on the outbreak of the Turkish-Balkan War in 1908, and then took up private practice in San Antonio, Texas.

The outstanding traits of Doctor Miller were

told in her obituary as follows:

"She acquired a fluent command of both the Syriac and Turkish languages, and at the time of her death had acquired a considerable library of books in the Syriac language which she had

read with pleasure.

"Doctor Miller's avocation was mathematics, for which she had marked ability, and to which she devoted what little leisure time she had. She was a member of the National Institute of Inventors. Among the inventions credited to her are a one-piece baseball cover, formed of an entirely new geometrical figure; a washing machine; a machine for picking and ginning cotton; machines for capping and stringing beans, gooseberries and cherries; a machine for skinning animals, and various rotary and combustion machines.

"Her death brought to a close a life of unusual

service and self-sacrifice."

EXECUTIVE SECRETARIES FOR COUNTY SOCIETIES IN PENNSYLVANIA

The Pennsylvania Medical Journal for December describes a plan for promoting the employment of full-time lay secretaries by County Medical Societies, as follows:

"At the May, 1932, meeting of the State Society Committee on Public Relations, Secretary Donaldson in discussing Chairman Alexander's report introduced the suggestion that component societies with one hundred or more members might with profit consider carefully the employment for the next two or three years at least of a full-time executive secretary, a layman. This proposal was discussed at various councilor district meetings held throughout the summer and fall. It was also freely discussed in the report of the Committee on Public Relations published in the September Journal. Adoption of the plan was advocated by President Charles Falkowsky, Jr., in his inaugural address published in the October Journal. The report of the Public Relations Committee above referred to was again published in the handbook distributed at the annual session of our State Society, as was also the resolution adopted by the Lycoming County Medical Society, which heartily endorsed the suggestion that a number of comty medical societies combine for the employment of an executive secretary.

"It was decided that the subject of the engagement of multiple executive secretaries by groups of component societies be brought specifically to

GASTRIC FABLES . . .

A Tale of Eating One's Way to Sleep

The doctor meant well when he advised his "nervous" patient to take a biscuit and a glass of milk before retiring. He felt sure the patient would find the rest and sleep she eraved by diverting the flow of blood from the brain.

But he didn't reckon with the vagaries of the stomach. There was no sleep—but a sleepless tossing around in bed because the stomach rebelled against the untimely hour at which it was put to work. It put its energies into action with a vengeance and hyperactivity with hypersecretion was the painful result.

CAL-BIS-MA came to the rescue. A teaspoonful in half a glass of water neutralized the excess acid and soon convinced the stomach that there is no use bucking fate in the guise of medical science. The patient got her sleep and rest.

Cal-Bis-Ma is a combination of calcium and magnesium carbonates, sodium hicarbonate, bismuth and colloidal kaolin, blended into a palatable powder. It neutralizes excess gastrie acidity quickly, efficiently and with lasting effect.... We will gladly explain the therapeutic merits of Cal-Bis-Ma and send a professional trial package for the asking..... Send for it.

IN GASTRIC HYPERACIDITY - CAL-BIS-MA

WILLIAM R. WARNER & CO., Inc., 113 WEST 18th STREET, NEW YORK CITY

Please mention the JOURNAL when uniting to advertisers

(Continued from page 60-adv. xxiv)

the attention of members of the State Society, exclusive of Allegheny and Philadelphia Counties, by means of a return or double post card. In keeping with the wise policy of leading our members to think more in terms of their councilor district, the return post cards with questionnaire were addressed to the respective district councilors."

The post card sent to the district councilors reads as follows:

"Post Card"

"The members of our State Medical Society who read the reports in the September Pennsylvania Medical Journal, or who will read the Minutes of the 1932 session in the November Journal, or who have been reading the A. M. A. Journal recently, must realize that the economics of medical practice and the relations of the medical profession to changing social conditions in the nation transcent in significance all other subjects collateral to the actual prevention and relief of sick-The Allegheny and Philadelphia County Medical Societies testify that their public relations have been improved by the employment of laymen as executive secretaries. The employment of such by groups of other county medical societies throughout the State has been highly recommended by medical society officers who have studied the problem. The subject of the employment of multiple executive secretaries is to be discussed at our Secretaries' Conference on December 6, which county society editors and chairmen of public relations committees will attend. In order that the Trustee and Councilor for your District may speak with authority at that time. your prompt use of the attached post card is earnestly requested."

(Reverse Side)

"I believe that the value of medical service to the people of Pennsylvania may best be maintained on the basis of personal and confidential relationships, which are possible only between the patient and the private practitioner of medicine; therefore, I do (do not) support the proposal that the County Medical Society, of which I am a member, join with an appropriate group of neighboring county medical societies to employ a layman as executive secretary to the group; therefore,

"I will (will not) in conjunction with a sufficient number of members of that group contribute \$5 annually for 1933-4-5 toward the employment of such secretary who is to be coached by representatives of State and county societies, and devote his full time to improving relations between the medical profession and the public in my district.

"Name "Address

ANNUAL REGISTRATION IN PENNSYLVANIA

The December issue of the Pennsylvania Medical Journal calls attention to the Annual Registration of physicians in the following editorial:

"The Department of Public Instruction has duly sent out a registration form for 1933. You attention is called to the necessity of taking care of this annual feature. It is just possible some of the physicians may have thrown the registration form sent to them in the wastebasket, with the misunderstanding it was advertising matter. We advise our membership not to delay, because the card specifically states that registration must take place on or before January 1 of each year. Print name in full, office address, street, and number the city and town must be given, also the state, as there are certain registrants not living in the State of Pennsylvania. It is also necessary to give your 1932 medical registration number. Do not send cash but remit by check or money order for the registration fee of \$1, made payable to the State Board of Medical Education and Licensure, to Harrisburg, Pa.

"The form also requests those practitioners who have retired from the practice of medicine to notify the State Board of Medical Education and

Licensure."

BOOK REVIEWS IN THE INDIANA STATE JOURNAL.

The attitude of the Journal of the Indiana State Medical Association toward book reviews, as shown in the following editorial in its November issue, is very different from that of those Journals in which the only book reviews are those of books published by houses which advertise in those Journals:

"A new book is written and the publisher sends a copy to a medical journal for review. If the reviewer is too severe the publishers will cease sending books so that particular journal and its library will suffer: if the reviewer is too easy and writes in glowing terms the publisher will send other new books in great number and will quote the review in order that sales may be made. Those who read the reviews may be misled in the Very recently as we latter case. were looking through a journal (not this one) a title caught our attention. The review was read and it was favorable enough to cause us to purchase the book. Actually the book was worthless. It was poorly written and illustrated, not well arranged, of doubtful authenticity, and was simply a rehashing of other much better treatises. We found ourselves stung to the tune of several dollars. In the past few years we have reviewed several books for this Journal and others. We have taken the position that the only honorable thing to do is to give a eandid opinion after a rather careful study of the book. Many of the reviews have been unfavorable and we have somtimes been inclined to think that we have been too drastie. The recent episode mentioned above has cured us of that feeling. We shall make reviews as heretofore, exeept that we shall not feel a bit bad when we call a rotten book rotten."

Diuresis is recommended in many forms of Heart Disease as an adjunct to other appropriate treatment.

FULL-TIME SECRETARY FOR KANSAS

The President of the Kansas Medical Society, writing in the October issue of the Journal, regarding the wisdom of employing a full-time secretary says:

"For the past several months, the president's office has received much literature bearing on the merits of the whole-time secretary and citing the experience of States which have adopted same.

"I find two opposing views within the State Society: honest views coming from some of our most sincere minds whose desires and ambitions are totally wrapped up in the best accomplishments for the Society. Your president has tried to make an honest study of this important question. In employing a full-time secretary we might make a great step in advance, or failure and dissension might follow. I have watched with much interest the Sedgwick County Medical Society; they feel they have succeeded. Yet others call attention to the large number of physicians who remain out of the society in Sedgwick County.

"I wonder if we are ready for this advanced innovation. I have read much literature on the subject; the preponderance was in favor of the full-time secretary. Yet, I am quite unfamiliar with its workings. How little, then, must the average practitioner know who has made no study of the question.

"Are we really ready for the employment of a whole-time secretary? Is the proper type of secretary easily secured? Will this cut down our numbers to hurt? Will it increase our budget to any marked degree?

"Is a medical journalist to be retained? Is a physician to be retained as secretary? I have always favored a layman as lobbyist for the legislature; he can be less modest and at the same time sincere.

"To my friends who are sineerely supporting this measure, I wish to state I am not opposed to it I am truly asking myself these questions."

FOR THE TREATMENT OF CHRONIC ARTHRITIS

Many clinicians hold to the theory that arthritis is due to a streptoeoecic infection. Subcutaneous injections of streptococcus vaccines, both autogenous and stock, have been used for many years with indifferent results in the treatment of arthritis.

A strain of Streptococcus viridans that has been under cultivation, for nine years or more, is of low virulence and safe for intravenous injection, is now available and is in growing use in the treatment of chronic arthritis. This new biological is a product of the Lilly Laboratories. The basis upon which its use is advocated rests upon the work of Drs. Clawson and Wetherby, of Minneapolis, Minnesota, and the results they obtain in administering a streptococcus vaceine, intravenously, in over five hundred patients.

Streptoeoccus Vaccine (Intravenous), Lilly, is not the ordinary streptococcus vaccine. It is a monovalent vaccine prepared from a strain of Streptococcus viridans isolated from a ease of acute rheumatic fever. It is available in 20 ce. rubber-stoppered vials. A booklet will be sent upon request addressed to Eli Lilly and Company, Indianapolis, Indiana. See page xii.—Adv.

PNEUMONIA

The most recent statistics dealing with pneumonia indicates its successful control in a large number of cases. In 707 cases of pneumonia in which Type I Antipneumococcie Serum was used, the death rate was 18.5% as

compared with the untreated eases, in which the death rate was 30% in 553 eases. When serum was used within 72 hours after the onset, the death rate was 10.7% in 177 cases.

Its refinement, as well as its standardization in units, gives the physician adequate information, so that the dosage can be correctly estimated from the

results achieved.

Full information will be supplied by the LEDERLE LABORATORIES and communications may be addressed to them at 511 Fifth Avenue, New York City. See page vi-vii.—Adv.

WHAT IS MALTCAO?

Malteao is a scientifically prepared health food consisting of pure sugar. malt, eocoa, partially defatted milk, and liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in grains and vegetables.

VITAMIN "D"

Winter is a jailer who shuts us all in from the fullest vitamin D value of sunlight. The baby becomes virtually a prisoner, in several senses: First of all, meterologic observations prove that winter sunshine in most sections of the country averages 10 to 50 per cent less than summer sunshine. Secondly, the quality of the available sun-

shine is inferior due to the greater distance of the sun from the earth altering the angle of the sun's rays. Again. the hour of the day has an important bearing: At 8:30 A. M. there is an average loss of over 31%, and at 3:30 P. M., over 21%.

While neither Mead's Viosterol in Oil 250 D nor Mead's 10 D Cod Liver Oil with Viosterol constitutes a substitute for sunshine, they do offer an effective, controllable supplement especially important because the only natural foodstuff that contains appreciable quantities of vitamin D is egg-yolk. Unlike winter sunshine, the vitamin D value of Mead's antirachitic products does not vary from day to day or from hour to hour. See page xxxii.—Adv.

PAIN!

For the treatment of pain and stiffness accompanying rheumatic and other disorders in the extremities, the application of heat is the most useful single measure known.

The local application of heat has a pronounced effect upon the circulation of the blood and lymph. It results in the relaxation of tissues, in improved metabolism and in helping to carry away the various exudates, inflamma-tory products and bacterial peisons deposited in the diseased joints and inflamed nerve sheaths.

Experience has demonstrated that there is no more effective application for d'lating the superficial and deep vessels than through the use of Anti-phlogistine. Its heat-retaining qualities, coupled with its high glycerine content and other components, produce an intensive hyperæmia and causes the blood to flow in larger quantities from the deeper tissues to the surface under treatment. Thus, through the dilatation of the blood-vessels and the locally increased osmotic exchange, the pathological products are poured in larger quantities into the blood and there destroyed.

For the pain, stiffness or swelling associated with arthritis in the wrists ankles, hands or feet; for sprains and strains; in fibrositis of the palmar or plantar fascia in the manipulative treatment of flat foot, where muscular re-laxation is desired, the use of Anti-phlogistine is always indicated. Physicians are invited to write to the Denver Chemical Mfg. Co., 163 Varick Street, New York, for sample and literature. See page ii.—Adv.

\LIXIR COLD TRIBROMIDE

(Pre-eminently a neurosedative and antispasmodic)
Used essentially for the treatment of WHOOPING COUGH. Other
Therapeutic Indications: Bronchial asthma, chorea, migraine and petit
mal. In four-ounce original bottles. A teaspoonful three or four

mal. In tour-ounce original times a day after meals.

THE RELATION OF EXOPHTHALMOS TO NASAL SINUS DISEASE* By RAYMOND W. HAWKINS, M.D., ROCHESTER, N. Y.

FEW signs in medical practice cause more alarm to the patient and more concern to the physician than exophthalmos. Four general types of nasal sinus pathology are capable of producing this condition. Firstly, acute or chronic infection in the sinuses; secondly, cavernous sinus thrombosis of nasal origin; thirdly, benign tumors and fourthly, malignant disease.

Exact figures as to its incidence are difficult to obtain since exophthalmos occurs in such a variety of conditions and is a sign rather than a disease entity. The clinical observation of most of us, however, is that true nasal sinus exophthal-

mos is a rather unusual experience.

Davis states that in twenty years of practice Logan Turner saw fifty-nine cases of orbital edema and orbital abscess. The author himself observed thirty-eight cases of proptosis of which twenty-eight were from disease in the sinuses, and five were due to cavernous sinus thrombosis. In Fuchs clinic Melter gives the incidence of exophthalmos as one case in 9,000 clinic admissions. The Heidelburg Clinic reports that from 1913 to 1920, there were 274 cases of orbital complications out of 6,494 or 3%.

It is generally accepted that the commonest cause of inflammation of the orbit is suppuration of the ethmoids in children and the frontals in adults. A consideration of the anatomy of the region makes this readily understandable. More than two-thirds of the wall of the orbit is made up of thin bone which is also the wall of a sinus. Within these thin walls the sinus cells show great variation. An anterior ethmoid cell may push laterally to form part of the roof of the orbit. Onode has described thirty-eight different formations in the relation of the posterior ethmoids and sphenoid.

The bony partition itself is perforated by many small openings, each one traversed by vessels and nerves. Through these small perforating veins the venous system of the mucous membrane of the sinus communicates with that of the orbit. Some more or less constant channels occur—ethmoid veins emptying into the superior ophthal-

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

mic vein. This rich anastamosis furnishes an extremely fertile soil for the spread of infection into the orbit.

Four general types of pathological condition require discussion as producing exophthalmos.

Firstly—Infections in the nasal sinuses. Acute empyema of the frontal sinus or one of the eth-moid cells is the most common cause. The path-way of the infection into the orbit may be by direct extension through one of the minute formamina, by thrombophilebitis of the small veins, through dehiscences in the bony wall, or by trauma or necrosis of the common wall.

When infection enters the orbit, the first reaction of course is edema. In this stage vigorous intranasal treatment is effective. With the formation of pus, one has to deal with a figure eight abscess, which will require thorough drainage of both cavities. If the orbital periosteum is not perforated, it should be carefully preserved. Pus from the frontal sinus enters the orbit through the thin bony floor just to the inner side of the orbital notch, causing maximum swelling in the inner third of the supra-orbital ridge, and pushing the orbital contents forward, down, and out. Pus from the anterior ethmoid cells presents near the posterior end of the lacrimal sac, displacing the eye forward and down. Suppuration in the posterior group pushes the eye forward.

Chronic orbital abscess may occur with exophthalmos of several months or even years duration. Coakley reports such an abscess from a chronically infected frontal sinus in a patient of 73 who had proptosis for three months. Johnson cites two cases, one of four months, and one of three years duration where drainage of a frontal abscess gave prompt relief.

When the maxillary sinus is involved the orbit is usually invaded through an area of bone necrosis, although edema without sequestrum formation or metastasis through venous channels does

occur.

Terrien, in (the French journal) La Progres Medical in 1930 describes osteoperiostitis which he believes to be syphilitic in origin, and which affects the region between the greater and lesser wing of the sphenoid bone, causing what he terms

the syndrome of the sphenoid sinus. Exophthalmos occurs from venous stosis. There is sensory motor and special sense disturbance, viz., anesthesia of the cornea, ophthalmoplegia, and impaired vision. He cites a case of severe trauma causing hemorrhage into the sphenoid cavity with much the same symptoms.

Second of the group of causes of exophthalmos is cavernous sinus thrombosis. This condition is the most acutely serious of those encountered. Faulkner divides the portals of entry of the venous infection into four anatomical divisions—anterior, from the lips or face, internal, from the sinuses or trauma to them, interior, from the tonsils, teeth and superior maxilla, and posterior from infections in the ear. In 140 cases collected by Dorland Smith only 9% originated from the sinuses.

Benign tumors, the third group, include mucocele and osteoma. Mucocele is defined as a closed distension of a sinus cavity from accumulated mucous. It occurs usually in the frontal or anterior ethmoid cells, may be found at any age, and is due to some type of obstruction to the The exophthalmos produced is often marked, and the whole condition is characterized by an extraordinary chronicity and freedom from inflammatory reaction. Osteomata are very rare, but three cases with unilateral exophthalmos are reported by Benedict. There was transitory swelling of the lids for several years before exophthalmos developed. All three had failing vision and symptoms were present for from five to eighteen years.

Exophthalmos from malignant disease is usually a late manifestation. The most common site of origin is the ethmoid labyrinth. About twice as many cases of sarcoma as of carcinoma are reported. The exophthalmos is progressive, and in unfavorable cases is extreme.

Diagnosis of the cause of the proptosis is usually simple, but in some cases may be extremely difficult.

In exophthalmos from infections in the sinuses, there is present typically purulent sinus disease, with symptoms of acute orbital infection. The onset is sudden, with fever, prostration and pain in the eyeball radiating into the orbit. Protrusion of the globe develops rapidly, with limitation of motion of varying degrees, up to immobility. Diplopia and reduction of visual acuity are noted. Local signs of inflammation are edema of the lids, often intense, and chemosis in severe cases. Pus may not be seen in the nose, but the common diagnostic procedures will demonstrate its presence. In chronic abscess, of course, the picture is much less alarming.

Early cavernous sinus thrombosis from the accessory sinuses may give local orbital symptoms suggesting orbital cellulitis. The disease progresses more rapidly, however, giving marked chemosis, early sixth nerve paralysis, followed

by involvement of the third, fourth and ophthalmic branch of the fifth. The patient is desperately ill with frequent chills. The orbital edema is of a bluish color and in later stages extends to the face and the other eye. In questionable cases the diagnosis settles itself in two or three days.

Benign tumors are all characterized by extraordinary chronicity and freedom from inflammatory reaction. Nasal examination is usually negative, unless the swelling pushes in the lateral wall.

The diagnosis of malignant tumors, as far as being a cause of exophthalmos, is usually made before orbital involvement occurs. The possibility of an early neoplasm being at the base of a purulent sinus infection was forcibly demonstrated in a recent case which came under my observation where exophthalmos developed within twenty-four hours, but persisted despite treatment of the acute infection. A squamous cell carcinoma of the ethmoid was later diagnosed.

The treatment of orbital cellulitis and abscess varies with the severity of the symptoms. Cases of pure edema are best treated intranasally. Logan Turner was able to cure fourteen of his fifty-eight cases in this manner. In children with ethmoid suppuration relief of congestion and suction or irrigation will bring a cure of the exophthalmos and a relief of symptoms in twenty-four to forty-eight hours. Adults may be cured by simple irrigation, but usually require some type of operative procedure. This may be intranasal, external, combined, or drainage of an orbital abscess. Whatever type of operation is employed, it should be sufficiently radical to insure adequate drainage, both of the infected sinus and the orbital pus.

Cavernous sinus thrombosis from a focus in the sinuses is an indication for immediate, complete and radical drainage of that sinus. Blood transfusion is recommended by Eagleton.

The prognosis in lesions producing exophthalmos from the nasal sinus varies, of course, on the pathology. Benign tumors have a good prognosis as to life. The impairment of vision depends on the duration of the symptoms. On the other hand cavernous sinus thrombosis and malignant disease give a very bad prognosis. Of a series of 684 cases of orbital inflammation recently reported, the mortality was given as 14%. Birch Hirchfield, in a similar series found 17%, death being due to meningitis, brain abscess, or cavernous thrombosis. Davis states that cases of orbital suppuration of sinus origin do not usually suffer permanent impairment of vision, and that in a series of sixty-two cases of his own and Logan Turner's, only one became blind.

It may be of interest to present two case records of exophthalmos of nasal sinus origin.

Case 1. W. B., a farmer boy of 14, came to the office on February 4, 1929, complaining of

headache and protrusion of the left eye. His family and past history were negative. Following a cold ten days before, he had profuse purulent discharge from the left nostril. One week before examination his left upper lid hegan to swell, and the following day the eye protruded. He had visited his physician twice. Left frontal headache, gradually increasing in severity, had been present since the onset of the nasal discharge.

Examination showed a well developed boy, who did not look acutely ill, but was in evident pain. T. 100. Pulse 90. There was considerable edema of the left upper lid, less of the lower, and marked protrusion of the globe down and out. Extra ocular movements were limited and diplopia was present. The bulba conjunctiva was only slightly reddened. On nasal examination the left cavity contained much pus, overflow was seen in the middle meatus, and both the left frontal and antrum were black on transillumination. The remainder of the examination was essentially negative.

Because the patient was not acutely ill, intranasal treatment only was begun. Both the frontal and antrum were carefully irrigated with
saline. Quantities of broken down pus returned
with the irrigating fluid. After two irrigations
the pain became much less, and the exophthalmos
began to subside. Continuing the daily irrigations, the diplopia had disappeared completely in
five days, along with the external signs of inflammation. Frontal and antrum washings hecame clear in ten days.

Case 2. D.M., a boy of 13, was seen by Dr. Lerner on November 23, 1931, in the Eye Clinic of the Rochester General Hospital. The family and past history were irrelevant, except for recurrent tonsillitis for the past five years. Four days before admission he attended school, but in the evening complained of pain in his right eye. He gave no history of trauma, but did have a slight cold. Later in the evening the upper lid became slightly swollen. The following day both lids became edematous, and protrusion of the ball was noted. Right frontal headache and fever developed. His symptoms increased in severity until two days later he came to the Out Patient Department. The following findings were noted: T. 103. Pulse 96. The right upper lid is intensely reddened and swollen, the lower less so, and both are tender to touch. Exoplithalmos is marked, with limitation of extra-ocular movements to 2° or 3° in all directions. The bulbar conjunctiva is chemotic. A slight exudate covers the cornea. The left eye is negative except for some edema of the upper lid. A diagnosis of orbital cellulitis was made, and the patient referred to the hospital.

General examination showed a well developed boy who seemed bright, mentally clear, but in considerable pain. Eye findings were as above. Nasal examination revealed no pus in the right middle meatus, and very little nasal congestion. The cars, throat, and general physical examination were essentially negative on probing the right naso frontal duct and bulla cell, a considerable quantity of pus was liberated. X-ray confirmed right maxillary, ethnicid and frontal sinuses.

Since some drainage was occurring, it was hoped the acute symptoms might subside by shrinking the membrane and applying suction. By the following night, however, even though drainage was profuse, the boy became definitely sicker, the temperature reached 104.5, with increasing lid edema and chemosis. Edema extended over the right frontal region across the midline. The white blood count showed 10,800 cells, of which 81% were polymorphonuclear.

Under general anesthesia and through a Killian incision, the right frontal sinus and anterior ethmoid cells were opened externally, and the bulla cell drained into the nose. Much pus was found in the sinuses, from which hemolytic staphilococcus albus was obtained. On pushing the orbital contents away from the floor of the frontal sinus, the whole region seemed bathed in thin pus, which was free in the orbital cavity. There was no thickening of the frontal mucous membrane. A large rasp was introduced intranasally into the right antrum for drainage through the inferior meatus.

The post operative course was stormy. On the first day, the temperature reached 105.6 with symptoms of meningeal irritation. Spinal tap showed clear fluid, 25 cells and a negative globulin test. After three days these symptoms cleared, but marked swelling developed in the soft tissues from the outer angle of the orbit to well back of the auricle. Two blood cultures at an interval of four days showed colonies of staphlococcus albus. Repeated incisions in the scalp were made over a period of two weeks, and a cervical abscess drained. By one week after the operation all the swelling about the eye had shifted to the soft tissues laterally, the exophthalmos had disappeared, and full rotation of the globe was possible. The sinus operative wound closed completely without drainage in three weeks. At this time a right otitis media developed but cleared without operative interference. One month postoperative, the lad developed osteomyelitis in the frontal and parietal bones, with an underlying extradural abscess. Since this focus was opened by Dr. Ward Williams the progress has been slow, but complete recovery seems certain.

In conclusion, the purpose of this paper has been to summarize briefly the relation of the various types of nasal sinus pathology to exophthalmos, and to point out the importance of recognizing this relationship as the first step in any successful treatment of such cases.

Discussion: A. M. Rooker, M.D., Niagara Falls, N. Y.—Dr. Hawkins was so thorough in

his presentation of the subject that it leaves very

little to be said in regard to it.

In exophthalmos due to benign causes the most frequent which I have encountered are those caused by mucocele. These present an extreme amount of exophthalmos frequently together with outward and downward displacement. There is a very slow onset and the response to the intranasal operative procedure is very satisfactory. In my cases I have been happily surprised to find that the eye has gone back to a perfectly normal position. I agree with Dr. Hawkins that the acute inflammatory conditions in young children respond well to intranasal operation. The older they are, the more frequently do we have to use the external operation.

The one case I wish to cite to show that we must not be led astray by our eye and nasal symptoms is that of a young man of 20, referred

with a temperature of 103.5, with considerable periorbital edema and history of rapid onset, with the nose on that side almost completely closed with acutely congested membrane. When the nose was shrunken with cocaine and adrenalin, the periorbital edema subsided so that he could open his eye. He was immediately hospitalized and operation was deferred even though he did seem extremely toxic. That night he became delirious, though the periorbital edema had not increased and the nose was somewhat less congested. Upon calling in his regular physician and having him go over him again, a short distressing cough, with rather hurried respirations, made me feel that probably we had another factor to contend with, and we found a beginning central pneumonia from which he died within 36 hours. You can imagine the gratification experienced by not having operated this case.

EXOPHTHALMOS—ITS OCULAR SYMPTOMS*

By HAROLD H. JOY, M.D., SYRACUSE, N. Y.

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

Exophthalmos is the cardinal symptom in most diseases of the orbit, and in some intracranial vascular lesions. It is an important sign in certain metabolic and systemic affections, and is frequent in skull malformations.

Its presence calls for:

1. A careful history.

2. Examination of lids, palpebral fissure, conjunctiva and cornea.

3. Palpation of orbit and globe, noting points of resistance and tenderness, as well as any mass which may be present.

4. Measurement of the proptosis with an exophthalmometer.

5. Examination of the globe for displacement and limitation of movement.

6. Vision and fields, and diplopia tests.

· Intraocular symptoms are omitted as they are to be presented by Dr. Reese.

7. Ophthalmoscopic examination.

8. X-ray of sinuses and orbit, and possibly of the optic canal.

Rhinological examination.

10. Complete physical and serological investigation, including metabolism tests in certain cases.

Exophthalmos depends upon disturbance in the relative size of the orbit and its retrobulbar contents-and to a lesser extent upon the condition of the external ocular muscles. As a consequence of this disturbance we may also have:

1. A wide palpebral fissure.

2. Eversion of lids, and ectropion of the lower lid.

3. Edema of lids and conjunctiva.

Desiccation and ulceration of the cornea.

5. Displacement of the globe. Limitation of movement.

7. Diplopia.

Visual symptoms

Pain and tenderness

Unilateral exoplithalmos is usually caused by local affections in or about the orbit, while bilateral exoplitlialmos is most often the result of systemic disease (Ruedemann)

I UNILATERAL EXOPHTHALMOS

Inflammatory proptosis may occur as the result of simple orbital cellultis or abscess, tenonitis, orbital periostitis or periostal abscess, or thrombosis of the cavernous sinus

Tever and other general symptoms are almost always present, and there is orbital pain of varying intensity. The lids and conjunctiva are chemotic, and the exophthalmos may be marked The position of the globe is usually primary (except in abscess and periostitis), and there is limited motility and diplopia, and frequently visual symptoms. It is sometimes impossible to differentiate the types of orbital inflammation, and often more than one type may be present

The chief points in differentiation are

In simple edema the signs are usually not so marked as in cellulitis, and the general symptoms are apt to be less severe

In orbital abscess the globe is usually displaced, and localized tenderness and fluctuation may occur, the abseess often breaking through the lid

In tenonitis

(1) The edema of the lids is only moderate while there is marked chemosis of the ocular conjunctiva, giving it a characteristic pale yellow

(2) The exophthalmos is of low degree, and it

may alternate from one eye to the other

(3) There is severe pain upon attempting to move the globe and extreme tenderness upon palpating it

(4) In severe cases the introcular tension may

be increased

In the purulent type of tenonitis the globe is extremely red and is usually fixed

In periostitis and periostial abscess there is (1) Severe spontaneous orbital pain, worse at night, especially in syphilitic cases

(2) Tenderness in the region of the lesion

(3) Displacement of the globe away from the lesion

Downward and temporally-if originating from the frontal sinus

Temporally (more rarely downward)—from the cthmordal sinuses

Upward—accompanied by edema of the cheek and lower hd if originating from the

maxillary sinus

Downward-in syphilitic periostitis of the orbital margin

Forward and temporally-in syphilitie periostitis of the orbital wall

In thrombosis of the cavernous sinus

1. Cerebral symptoms are almost always pres-

2 The inflammatory signs are more promment than in any other type

3 Edema in the mastoid region is usually present

4. Paresis of the external muscles is common

5 The exophthalmos usually extends to the other side within two to four days

6 The duration is short, almost always with a fatal termination

Mucococle of the frontal and ethmoidal sinuses may cause a slowly progressing proptosis with displacement and limitation of movement, and with little or no evidence of inflamination

X-ray shows a punched out hole in the orbital wall, and a mass can often be palpated

If from the frontal sinus

The displacement is often down and temporally

2 There is usually a swelling in the superior ınner orbital angle.

3 The root of the nose may be flattened out because of naso orbital hyperostosis

4 The upper lid is often smoothed out and the palpebral fissue narrowed

Pain is usually present in the frontal sinus 6 Visual and field changes occasionally occur

If from the ethmoid cells

1 Exophthalmos is one of the first symptoms to appear.

The displacement is usually down and temporally, but if from the posterior ethnioids it may be directly forward

A history of head colds or sinusitis is important in the diagnosis of pyocoele which in other respects is difficult to differentiate from orbital tumor.

Sclerosis of the retrobulbar tissues is a rare cause of exophthalmos There is disappearance of lacrymation, irregularity in position and function of the lids, limiting of movement, decreased vision and pain

In pulsating exophahalmos there is marked edema of hids and conjunctiva with widely dilated veins, and distention of the scleral veins is a varying degree of proptosis and the globe is usually displaced laterally or downward, more rarely directly forward. Movement is restricted. The eye can be pressed especially temporally. back, and a pulsation felt and occasionally seen A bruit is audible not only over the eye but often over the whole half of the skull, and the patient is conscious of a continuous roar. Intensity of the bruit and of the pulsation is increased upon raising the orbital blood pressure, and is diminished by pressure over the carotid Diplopia is frequent and vision is usually seriously affected Orbital pain is common, as well as vertigo and impaired hearing Corneal anesthesia and diminished accommodation are not unusual; and glaucoma or cataract may supervene.

Intermittent exophthalmos is rare. It usually follows coughing, straining or bending over, and is marked by sudden exophthalmos which may be of high degree, and is usually accompanied by pain. It is recurrent and loss of vision may occur.

Retrobulbar hemorrhage is usually traumatic in origin. There follows a rapidly developing exophthalmos in the primary position, with restricted motility, accompanied by ecchymosis of the lids and by subconjunctival hemorrhage (unless the hemorrhage is subperiostial). Visual symptoms may be present if the optic nerve or globe are injured.

Emphysema is characterized by a sudden proptosis accompanied by marked swelling of the lids, with crepitation. The symptoms appear, not as a rule at the time of the injury, but some time afterward, usually upon blowing the nose, thus forcinging air into the orbital tissues. The palpebral fissure is narrowed and the globe is in the primary position and can easily be forced backward.

Orbital tumor usually manifests itself as an acquired unilateral, slowly progressing exoplithalmos, with displacement, and restricted motility. A mass can often be palpated, and there are visual symptoms if the optic nerve or globe are involved. The presence of pain and tenderness, and edema of lids and conjunctiva depends upon the situation, the nature and the extent of the tumor. The further back the lesion the later the appearance of proptosis. The tumor may be vascular, cystic, bony, of the soft tissues, or of the optic nerve (Roemer).

Vascular tumors are rare. Pulsating hemangiomas cause erosion of bone and congestion of the neighboring soft tissues (Benedict). Telangiectases may be seen through the skin of the lids, and cavernomas may cause serious visual symptoms by pressure on the optic nerve.

Dermoid cysts frequently cause displacement of the globe down and nasally. Echinococcic cysts usually exhibit pain and inflammation in the surrounding tissue during their development. Encephalocele or meningocele through the superior orbital fissure may cause pulsation: upon emptying the cyst by pressing the globe backward symptoms of increased intracranial pressure are often produced.

X-ray is important in the diagnosis of bony tumors. Osteomata usually start in the sinuses and penetrate into the orbit. The optic nerve is usually involved as the first symptom if the osteoma originates in the sphenoidal sinus. Exostoses are most frequently situated on the roof or upper inner wall.

Sarcomata are the most frequent of the primary tumors of the orbit. Their growth is rapid

with no inflammatory signs. Primary carcinoma produces much irritation of the invaded structures. There is early disturbance of muscle function, and the globe may be drawn to one side and fixed to the orbital wall. Tumors originating in the sinuses usually cause inflammatory symptoms, while metastatic orbital growths develop without irritation. Intraocular tumors may extend into the orbit without producing irritation or there may be violent inflammatory reaction.

In tumors of the optic nerve vision fails early (except in glioma). Exophthalmos also appears early, and increases slowly and without pain. The globe is proptosed directly forward, or slightly downward and temporally. The course is comparatively benign.

It may be difficult to differentiate a tumor from orbital gumma, which is most frequently situated on the upper wall at the level of the superior orbital fissure. Edema of lids and conjunctiva is usually present. Corneal anesthesia is common, and neuroparalytic keratitis may occur. There is progressive proptosis with displacement; and often disturbed motility due to paralysis of the external rectus muscle. There is deep-seated spontaneous pain, which is worse at night. Iritis is not an infrequent complication. The Wasserman reaction is of course important in the diagnosis.

The so-called *pseudo tumors* include diffuse tuberculous infiltration, leukemic processes, diffuse lymphangioma, and chronic inflammation. The onset may be rapid or slow and insidious. The degree of exophthalmos is usually not great. Displacement, diplopia and restricted motility are common, and there is often edema of lids and conjunctiva. Visual defects are not rare. The symptoms may disappear spontaneously after a few months, but recurrence is frequent.

In external ophthalmoplegia there is ptosis and moderate exophthalmos in the primary position with restricted motility. The globe can easily be pressed back, but immediately sinks forward again.

II. (a) BILATERAL EXOPHTHALMOS IN CHILDREN

Infantile scurvy causes periosteal orbital hemorrhage resulting in proptosis usually accompanied by ecchymosis or edema of the lids. The onset is sudden and there is displacement forward, downward, and outward. Rapid and complete recovery follows anti-scorbutic treatment.

Christian's syndrome (diabetes insipidus) is characterized by exophthalmos with large defects in the bones of the skull, especially about the orbit. Visual symptoms are not infrequent due to involvement of the optic nerve or retina, or to desiccation of the cornea.

In chloroma or green blood tumor there is

cdema of the lids with exophthalmos. The parotid and other glands are often swollen, and corneal desiceation and panophthalmitis are frequent complications. The blood picture and greenish color of the child assist in the diagnosis. The discase always terminates in death.

Oxycephaly or tower skull causes a viariable degree of exophthalmos due to malformation of the orbit which may be confirmed by x-ray examination. The characteristic shaped skull cannot always be depended upon. Involvement of the optic nerve and nystagmus are usually present.

Although exoplithalmos occasionally occurs in hydrocephalus and rickets it has relatively little diagnostic importance.

II. (b) BILATERAL EXOPITHALMOS IN ADULTS

The most frequent eause of proptosis is exophthalmic goitre. In most cases it is the last cardinal sign of Graves disease to appear. amount of exoplithalmos is not proportionate to the severity of the disease, and while it is usually bilateral, it may be of unequal degree. The globe assumes the primary position, and its motility is seldom affected. There is occasionally periodic edema of the lids, and there may be either increased or decreased lacrymation. Vision is usually not affected if the cornea is not involved. Before discussing the classical signs which we associate with exoplithalmic goitre, it should be mentioned that they are occasionally found in nephritis and in ocular paralyses, and may be due to other toxemias and poisons, and to some diseases of the central nervous system. signs are nevertheless present in over eighty per cent of all eases of exophthalmic goitre. They

- (1) Dalrymple's sign—consisting of a wide palpebral fissure.
 - (2) Stellwag's sign-infrequent winking.
 - (3) Von Graef's sign-in which the rotation

Discussion — Charles A. Hargitt, M.D., Brooklyn, N. Y.: I am sure that we can all agree that the problem of exophthalmos is one that well descryes a thorough review from time to time. Furthermore, the proper consideration of this problem can be best undertaken in such a sectional meeting as we have here, for many phases of it require the cooperation of the rhinologist or laryngologist.

Dr. Joy is entitled to our heartiest congratulations upon the clear and logical manner in which he has presented the problem, as a whole, from the viewpoint of the ophthalmologist. In fact he has done it so well that it looks very easy. We all know, however, how of the globe and lid downward is not synchronous, the lid making a jerking attempt to follow.

(4) Gifford's sign—difficulty in everting the upper lid.

(5) Moebius sign-difficult convergence.

(6) Joffroy's sign — the forehead remains smooth upon looking upward.

(7) Another sign is sometimes found in early cases. It consists of four strike of congestion corresponding to the recti muscles.

A low degree of exoplithalmos may occur in hypathyroidism. There is edenna of the lids and weakness of aecommodation convergence. The individual is sluggish, has a dry skin and gives a history of gain in weight.

The proptosis occasionally observed in hypertension is not great. Opthalmoscopie examina-

tion assists in the diagiosis.

Asphyxia causes acute edema of the orbit with some exoplithalmos accompanied by intraoeular hemorrhage.

The proptosis in Mikulicz's disease is usually of unequal degree. There is swelling of the

lacrymal, salivay and parotid glands.

One of the earliest signs of trichinosis in about eighty per cent of the cases is edema of the orbit with exophthalmos of three to four millimeters.

Osteitis deformans (Paget's disease) usually occurs in elderly individuals. The exophthalmos is due to the deformity of the skull which has a characteristic appearance. The presence of hard tumor-like growths and the thickening of other bones, particularly the tibia, are important diagnostic points.

CONCLUSION

Exophthalmos is always significant. It almost always indicates a serious local or systemic disturbance. It may result in loss of vision, destruction of globe and lids, or in death itself. Early detection is important, but even more important is early diagnosis of the clinical cause.

highly individualistic some of these cases can be.

Dr. Joy does well to accentuate the importance of the unilateral exophthalmos, for there it seems to me, lies the chicf concern and responsibility of the ophthalmologist. I suspect that few, if any, of us see enough cases of this type that we can unhesitatingly and properly classify them. This is particularly true of the non-inflammatory unilateral exophthalmos. To illustrate this may I be allowed to very briefly describe two or three case, though I may be encroaching somewhat on Dr. Reese's field.

Over a period of eight years from 1923 to

a year ago, I followed a case of intermittent unilateral exophthalmos in a middle-aged maiden woman. The first development of it was a very gradual one. The eye was emmetropic, with a vision of 20/15. At its extreme stage of development, there was almost complete immobilization of the globe, with a moderate amount of proptosis, and a slight displacement temporally. There were intervals of almost complete remission of signs and symptoms. At one time her physician thought she exhibited some evidence of endocrine disturbance. There was never any enlargement of the thyroid gland. X-ray examination and nasal examinations never gave any clue to the cause. At times there would be a return or increase in the amount of proptosis following some nervous disturbance. The eye gradually changed from emmetropica to myopia of one and one-half diopters, without any demonstrable lens changes. During the past year, the exophthalmos has remained more or less stationary, but much less than in its periods of maximum development. There has been a gradual loss of vision with a developing optic atrophy. She always seemed extremely indifferent to her condition, and it was never thought advisable to strongly urge any exploratory operation of the orbit.

Another very recent case of unilateral exophthalmos exhibited some interesting variations in its development. A young man of 35 came into our clinic at the Brooklyn Eye & Ear Hospital three months ago. For the preceding few weeks he had noticed a gradually developing prominence of his right eye. At his first appearance at the clinic there was a moderate amount of edema of the lids and bulbar conjunctiva and beginning proptosis. The conjunctival and retinal veins were moderately engorged. During the period of investigation by laboratory, X-ray, etc., these signs became more marked. There was no

history of traumatism, nothing preceding could be palpated in the orbit, and no bruit could be detected, nor could any pulsation be detected upon pressure on the globe. Gentle pressure on a slightly accentuated fullness of the lower lid edema just below the inner canthus, elicited a slight pulsation. The x-ray and nasal examinations were entirely negative. He had been hospitalized during these investigations and toward the end of the second or third week, extensive retinal hemorrhage appeared. orbital exploration seemed imperative, and was made through an external canthotomy and entrance along the outer orbital rim, with section of the external rectus muscle. This permitted a thorough palpation of the orbital contents both inside and outside of the muscle cone. No tumor formation or unusual fullness could be identified. The rectus muscle was reattached, and the wound closed. Recovery from the operation was rapid and uneventful, with no change in the essential condition. Two weeks following the orbital exploration, a very distinct bruit was heard for the first time, over the right temple, and on backward pressure on the globe, a well marked pulsation could be felt. At this time, also, a paresis of the external rectus had developed. A ligation of the common carotid artery resulted in prompt obliteration of the bruit and pulsation, and a subsidence of the edema and proptosis to nearly normal, and improvement in the paresis of the external rectus.

Very briefly I mention the case of a young man of 39, a patient in the Kings County Hospital six years ago who made a spontaneous recovery from a cavernous sinus thrombosis. The vision of one eye was practically lost from extensive corneal ulceration and subsequent scar formation. One year later the vision of the other eye was 6/12 with a slight optic atrophy, a very slightly contracted field, and marked engorgement of the retinal veins remaining. There was practically no temperature reaction in this case, and hence, no septicemia.

Discussion—Jason L. Wiley, M.D., Auburn, N. Y.—I am impressed with the completeness with which Dr. Joy has covered this subject and with the strictness with which he has kept to the title of his paper. I have little to add. I should like to stress a few points made and mention one or two observations.

1. I think the statement "Exophthalmos depends on the relative size of the orbit and its contents" should be emphasized. The anatomy and mechanics of the forces holding the eye in position should be understood to intelligently deal with the abnormality under discussion.

2. In regard to measurement of the proptosis with an exophthalmometer. Repeated measure-

ments are important. First, to be sure of our diagnosis in cases of slight degree, and second, to keep track of the progress of the proptosis in all cases. Any method other than instrumental measurement is not reliable.

Two observations about cases secondary to nasal sinus infections. One word about x-ray findings. I believe rhinologists almost unanimously agree that a sinus can be very badly obstructed and infected and show nothing abnormal in the film. Of course, positive findings are of great aid.

Not infrequently swelling and proptosis are present early in these cases. Rhinologists consider it unsafe to operate early (I mean the first

few days). Vision is usually unt in danger until the eyeball is fixed or nearly so. It is hazardous to wait longer. I saw such a case in which the vision was lost a short time ago. The eyeball was fixed and absolutely blind from an obstruction of the central artery when first seen. We at least should insist that the rhinologist who wants to defer surgery after the globe is fixed understands the risk in regard to vision.

3. We should be careful not to let swollen lids mask the presence of proptosis. Equal care should be taken not to diagnose a case as exophthalmos in the presence of swollen lids when the position of the globe is normal.

4. Work recently done, in the Mayo Clinic I believe, strongly suggests that the proptosis of Graves' disease is caused by a disturbed metabolism of the orbital fat resulting in a waterlogged condition of this tissue. Dr. Joy's last statement cannot be repeated too often. "Early detection is important, but even more is the diagnosis of the cause."

EXOPHTHALMOS*

Its Pathology and Ocular Manifestations By ALGERNON B. REESE, M.D., NEW YORK, N. Y.

N the time allotted for this paper it will, naturally, be impossible to discuss all phases of the subject assigned. It will therefore be necessary to exclude some very important causes of exophthalmos, such as hyperthyroidism; sinusitis; ascending thrombophlebitis from infection of the face, nose, lids and lips; orbital syphilis and tuberculosis; intracranial neoplasms and abscesses; nasopharyngeal neoplasms; bone neoplasms and hyperplasias in and around the orbit; congenital narrowing of the orbital space as seen in oxycephalis and others. At the conclusion of the paper time will be allowed for the projection of some microscopic specimens showing various ocular changes produced by orbital lesions and other specimens illustrating causes of exophthalmos which have not been discussed in this paper.

The conditions here presented are not necessarily those most frequently encountered, in fact they have been closen chiefly because they are not commonly emphasized. They will include pseudo-tumors of the orbit, varix orbitae or intermittent exophthalmos, orbital hemorrhages, defects in the roof of the orbit, blood dyscrasias, high myopia and relaxation of the recti muscles.

1. Pseudo-tumors of the orbit. The first group of cases to be emphasized comprises the so-called pseudo-tumors of the orbit. Their importance lies in the fact that a chronic inflammatory proccss here simulates in every detail a new growth, thereby sometimes causing an incorrect diagnosis, the consequences of which may be serious. Exophthalmos may exist to any degree. No inflammatory signs are present but usually a firm, nontender and sometimes well demarcated mass is palpable in the orbit. One of the characteristics distinguishing this condition from an orbital neoplasm is its tendency to spontaneous regression over a long period of time, another point of difference between the two conditions being the fact that primary orbital neoplasms are most frequently encountered in the first twenty years of life, while pseudo-tumors are usually seen in people past middle age. Biopsy in these cases shows fibroplastic repair in all stages, from the denser hyaloid, almost anuclear tissue of long standing to the delicate fibroglia and richly nuclear tissue of more recent production. Foci of lymphocytes are scattered through this reparative tissue. Blood vessels are plentiful, their intima usually showing proliferation to such an extent that the lumen appears almost occluded, and their media

^{*} Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N Y., May 24, 1932.

and adventitia being thickened with sclerosis which has undergone hyaloid degeneration. These vascular characteristics explain a strong tendency to hemorrhage at biopsy.

The etiology of pseudo-tumors is unknown. There is no evidence of syphilis or tuberculosis. The theory that they are a very late manifestation of syphilis, which has run its course and therefore gives a negative Wassermann, is apparently borne out by the fact that they seem to recede much faster under the usual treatment for late syphilis, but the effect may be absorptive rather than specific. One patient, who was observed for three months, at the end of this time developed a septicemia with exophthalmos of both eyes, resulting in death, indicating that the lesion is caused by a low grade metastatic embolis from some focus of infection which in this particular case gave rise later to a virulent septicemia.

A case followed by Birch-Hirschfeld was diagnosed as sarcoma of the orbit. Exenteration was performed and a microscopical examination of the orbital contents showed the usual inflammatory process. Some months later the other eye gradually became proptosed to the extent of 12 m.m., with no pain and no sign of inflammation. The vision was practically lost as the result of a corneal ulcer due to exposure. The exophthalmos receded gradually and spontaneously over a period of several years, during which time the patient's health was good. Exhaustive study revealed no clue to the etiology. A similar case, known to the speaker, was diagnosed as orbital neoplasm and after exenteration microscopical examination of the orbit showed a low grade inflammatory process resembling the one already described. These pseudo-tumors of the orbit are not uncommon and it is therefore not advisable to perform a radical operation in the case of a suspected neoplasm in a person past middle age until the possibility of a pseudo-tumor has been eliminated.

2. Varix orbitae or intermittent exophthalmos. In the next group, consisting of varix orbitae or intermittent exophthalmos, the provocative factor is congestion of the jugular vein area. Here the exophthalmos appears upon stooping, after compression of the jugular vein, after holding the breath, after strong expiration, etc., and disappears when the patient is in the ordinary standing, sitting or lying positions. It usually appears about middle age, is apt to be in the left eye and is more frequent in men than in women. It is caused by varicosities of the orbital veins possibly due to an atresia of the foramen through which the jugular vein leaves the skull and is usually on the left side because the foramen is normally smaller on this side. Some cases show varicose veins of the conjunctiva, lid and other parts of the body. In congestion of the jugular area occasionally intracranial symptoms appear

which suggest the existence of intracranial varicosities. The prognosis as to life is good but seven out of 89 cases showed failing vision due to optic nerve atrophy and occasionally to orbital hemorrhage. In a case of this sort, which has been observed for two years and in which an orbital angioma was at first suspected, the patient's condition has remained unchanged and he has no troublesome symptoms unless venous congestion is produced in any of the ways previously mentioned.

- 3. Hemorrhage in the orbit. The next group, that of hemorrhage of the orbit, is often connected with some systemic disease. In infants the possibility of scurvy as an etiological factor must be considered. In this condition subperiosteal hemorrhages may occur anywhere in the body, a characteristic location being along the inner aspect of the femur, but occasionally they occur along the orbital bones and unless the underlying cause is recognized they may be mistaken for orbital neoplasms. Exophthalmos in rickets is perhaps more often due to periosteal proliferations although it may be caused by hydrocephalus or subperiosteal hemorrhage. In myelogenous leukemia a tendency to hemorrhage may be manifested spontaneously in the orbit. In severe compression of the thorax hemorrhage may appear not only in the orbit but under the skin of the face and neck, under the conjunctiva and in the retina, even in the absence of any injury to the head. This may be explained by the fact that the great and sudden increase of pressure in the thorax forces the blood into the area of the jugular vein. This force, transmitted by the valveless veins of the region to the tributaries, ruptures the walls of the latter and results in hemorrhage. A similar explanation will suffice for the orbital hemorrhages occurring during paroxysms of coughing and those observed in asphyxiated new born infants.
- 4. Defects in the roof of the orbit. In this group of cases a defect in the roof of the orbit allows the brain and meninges in the anterior fossa to form a hernia into the orbit, producing an exophthalmos which sometimes pulsates. When this is due to a congenital defect in the orbital roof it is called a posterior orbital encephalocele or meningocele. The more common anterior encephalocele or meningocele gives rise to a lateral displacement of the globe and, less frequently, to exophthalmos. These congenital defects of the orbital wall may not be evident until a considerable time after birth, sometimes as late as ten years. Hydrocephalus and brain tumors may also produce exophthalmos through defects in the orbital roof.
- 5. Exophthalmos from blood dyscrasias. In lymphatic leukemia a proptosis may be the sign which first prompts the patient to seek advice. This proptosis is due to hyperplasia of the lym-

phatic tissue in the auterior part of the orbit, especially around the lachrynial glaud, which is a part of the general lymphadenopathy common to this disease. Its excessive manifestation in the orbit is probably caused by obstruction to the lymph drainage. In chloroma there is an involvement of the flat bones of the skull with a secondary extension of the lesion to the orbit. The orbital hemorrhages occurring in myelogenous lenkemia have already been mentioned.

- 6. High myopia. A prominence of the eye may be produced by very high myopia. One case known to the speaker, with a unilateral myopia of approximately 30 D was investigated from all angles in an effort to explain the exophthalmos, before the myopia was appreciated as the cause. The eye protruded 4 mm. and a tarsorrhaphy was necessary for cosmetic reasons.
- 7. Relaxation of the recti muscles. A complete tenotomy of one of the recti muscles, for instance in an operation for squint, may produce a mild proptosis of 2-3 m.m. A similar mild exophtianos may also be observed in paralysis of the oculomotor nerve.

Projection of Microscopic Specimens

- A. Globe and orbital contents of a case of pseudo-tumor of the orbit which was exenterated. This showed the orbital tissue involved by a low grade proliferative chronic inflammatory process.
- B. Specimens which showed ocular manifestations from orbital lesions.
- 1. Melano-carcinoma of the orbit which arose from a naevus at the limbus.
- a. from pressure around the optic nerve there was papilledema, optic atrophy and thrombosis of a branch of the central retinal vain
- of a branch of the central retinal vein.
 b. from embarrassment of the vortex veins
- there was secondary glaucoma.
- e. from pressure on the sclera there was acquired hyperopia or pseudo detachment of the retina,
- 2. Basal cell carcinoma of the orbit (cylindroma).
- a. from pressure on the optic nerve there was papilledcma.
- b. from embarrassment of the vortex veins there was secondary glaucoma.
- c. from pressure on the sclera there was acquired hyperopia or pseudo detachment of the retina.
 - 3. Round cell sarcoma of the orbit.
- a. from marked exophthalmos there was an ulcer lagophthalmos with hypopyon.
- C. Specimens which showed causes of exophthalmos other than those mentioned in the paper.
 - Panophthalmitis:
 - a. from an ectogenous endophthalmitis.
- b. from a necrotic melano-sarcoma. The similarity of types a and b were noted.

- Orbital contents and globe in a case of metastatic orbital cellulitis from septicæmia. Pure cultures of embolic foci of the bacteria were present.
- 3. Three cases of congenital orbital cysts and globes. One ease accompanied a microphthalmic eye and two cases accompanied relatively normal eyes—the one having a typical coloboma of the optie nerve but the other showed a mass of congenital fibrons tissue over the nerve head and the diagnosls was thought to be an orbital neoplasm.
- 4. Orbital contents in a case of long standing arterio-venous aneurysm (carotid in the cavernous sinus) which had undergone spontaneous recession due to atresia and occlusion of the vessel lumina from proliferation of the intima.
- 5. Orbital contents in a case of septie thrombosis of the cavernous sinus. This showed a marked inflammation of the orbital tissue which was a big factor in the production of the exophthalmos. In thrombosis of the cavernous sinus of the marantie or non-septic type only 10% cause exophthalmos while in those of the septic type 72% cause exophthalmos. The reason that exophthalmos is more prevalent in the septic type is because the septic process spreads to the orbital tissues as demonstrated in the above specimen. Simple stasis and congestion of the orbital veins seldom causes exophthalmos because of the several avenues of venous return—veins of the face, sinuses, fossa temporalis and brain.
- 6. Orbital contents, extra-ocular muscles and globe in a case of trichiniasis. Numerous foci of the encysted parasite were present in the extra-ocular muscles and a secondary inflammation of the surrounding orbital tissues. It was pointed out that metastatic lesions of the orbit show a predisposition to implant themselves first in the extra-ocular muscles. Metastatic carcinoma and sareoma of the orbit characteristically implant themselves first in the extrinsic muscles.
- 7. Two cases of conglomerate tuberculosis of the posterior half of the eyeball with spread to the orbit and exophthalmos. The anterior half of the globe was relatively free of any inflammation.

Lantern slides were shown of:
1. exophthalmos in a case of lymphatic leuk-

1. exophthalmos in a case of lymphatic leuk æmia.

2. exophthalmos in a case of myelogenous leukæmia.

3. unilateral high myopia simulating exophthalmos. This is the same case quoted in the paper.

Discussion: Macy L. Lerner, M.D., Rochester, N. Y. Very few ophthalmologists are fortunate enough to possess such a collection of microscopie specimens relating to the subject of exophthalmos. Dr. Reese has covered the subject thoroughly and taught us a great deal about the hystopathology of exophthalmos.

My particular interest in Dr. Reesc's paper is

with reference to pseudo-tumors of the orbit. I am in accord with the essayist that these groups of cases are, perhaps, often mistaken for true tumors; and, consequently, misleading diagnosis may influence us in advising enucleation. There is not, perhaps, a more difficult problem in ophthalmology which confronts the ophthalmologist than that of a case of exophthalmos. It requires not only detailed ophthalmological studies and careful judgment, but also complete laboratory, x-ray and basal metabolic studies, before one is in a position to advise as to rational treatment. Too much stress has been laid in the last few years on orbital tumors in exophthalmos ignoring many other etiological factors.

I recall a few cases which, perhaps, belong to the group of pseudo-tumors. A man 65 years of age reported, complaining of a bulging right eye, blurring vision, lachrymation, and diplopia after looking at small objects for a few minutes. He also had difficulty in keeping the lids open. He had these symptoms for six months. He gave a history of having lumbago for 20 years, suffered from slight shortness of breath, was subject to frequent colds, and was chronically constipated. An operation for aspiration of bilateral hydrocele was performed eight years before. Physical examination revealed that he had an enlarged heart and emphysema. Nose and throat examinations, including X-rays of the sinuses were negative. The Wassermann was negative and complete blood studies revealed that he had 8% eosinophiles. Otherwise there was nothing abnormal.

Ophthalmological findings:

Visual Acuity: O.D. 6/20, and O.S. 6/10 Right globe was moderately pushed forward without apparent injection. Upper lids felt rather tight over the globe. There was definite limitation of globe inwardly, up, and down. Pupil reacted to direct, consensual light, and to accommodation. Ocular tension (tactile) normal. Ophthalmoscopy revealed nothing abnormal except incipient lenticular opacities, and moderate degree of sclerosis of retinal vessels.

The possibility of an echinococcus cyst of the orbit was considered. The blood was sent to Albany for complete fixation with the echinococcus antigen. The test, however, could not be done at the State nor in our own local laboratories because of not having the echinococcus

antigen.

This patient was under observation from June to January without any apparent marked changes in external appearance of exophthalmos. His visual acuity averaged from 6/20 to 6/7. Lachrymation and difficulty in keeping his lids open were his chief complaints. I did not consider it wise to recommend an exploratory operation on the orbit because of his age. There was no palpable mass, and the X-ray findings were nega-

tive; therefore, I did not feel justified in suggesting a radical procedure. He was referred to Dr. Palmer for X-ray therapy and kept under observation. At one time Dr. Palmer thought that the exophthalmos decreased slightly. The patient died shortly afterwards rather suddenly of coronary disease. Autopsy was not permitted, and it was impossible to obtain the eye for study.

Dr. Reese cited a case of very high myopia with a bulging eye which was a problem for diagnosis as to the cause of exophthalmos. I wish to report a similar case in my own practise where a woman past middle life complained of bulging of the left eye. She noticed it particularly after an automobile accident. There was no history of disease nor injury to the eye or head. She had fractured ribs, and suffered from considerable Her case turned out to be a medicolegal problem. This woman went through different examinations, and during an ophthalmological examination she discovered that she did not see well with her left eye. She was studied by a number of ophthalmologists and different opinions expressed to her.

Upon examination I found the lids were normal except for some tremor. No impairment of occular motility. Pupils were slightly unequal, the right one about 3 to 4 m.m., the left about 4 to 5 m.m. The pupils were regular, reacted to direct, consensual light, and to accommodation promptly. When testing convergence, I noticed that the left eye turned out considerably. Ocular tension (tactile) normal in both eyes. Her visual acuity with correction in right eye was 6/7, in left less than 1/60.

Ophthalmoscopy: O.D. Numerous vitreous opacities were observed floating freely in all directions, as well as peripheral lenticular opacities. Disk well outlined, outer half slightly grayish, showing a crescent on the temporal side. Retinal vessels were normal for her age. No lesions were seen in the macula nor periphery of fundus.

O.S. Media showed numerous opacities floating in all directions in a cloud-like manner. Opacities were of different shape and size. Disk was irregularly outlined, appeared very large, with a large area of peripapillary choroiditis atrophica. A large conus was also noted. A patch of choroiditis could be made out along the superior nasal retinal vessels. The macular region showed an old chorio-retinitis. Details of the fundus were seen with a —20.

X-rays of the sinuses, orbit, and physical examination showed nothing abnormal. There was not a single point besides the exophthalmos and rather vague symptoms to indicate that there was an orbital tumor. Still this patient was told that she had a retrobulbar tumor and enucleation was advised. This information was given to me by her a few days later, after I had made my diagnosis of progressive myopia with secondary

fundus pathology. I obtained six photographs of this patient dating from 1898, 1909, 1911, and 1932, and all these pictures show plainly the prom-

inenec of the left eye.

My feeling has always been that an exploratory operation or enucleation should not be recommended until we are fairly convinced that a true orbital neoplasm is present. In doubtful cases, or even in cases where a diagnosis is fairly well established as to the existence of a neoplasm, I wonder whether X-ray therapy, perhaps, would not offer a better solution. I recall Dr. Pfahler of Philadelphia once having a heated argument with the late Dr. Webster Fox about the treatment of orbital neoplasm. Pfahler contended that the best results are obtained from X-ray therapy in such cases when not interfered with surgically first. He substantiated this statement a few years later by reporting before the Section of Oplithalmology of the A. M. A. a number of cases of orbital tumors treated with X-ray showing excellent results. I am aware of the fact that treatment does not come into the phase of my discussion, but I wish to emphasize this partieular statement of Dr. Pfahler so as to keep us on guard in our differential diagnosis as to the ctiology and pathology of exophthalmos, and remind ourselves that we can do a whole lot more with conservative treatment.

Dr. Reese has not mentioned the type of exophthalmos of central origin. W. R. Brain, reeords in the British Medical Journal for November, 1931, that he has observed a number of eases of exophthalmos in which the condition was evidently of central origin occurring in association with signs elearly indicating organic lesion of the central nervous system. "Exophthalmos of this type may be associated with supranuclear ocular palsies, especially paralysis of conjugate vertical movement and convergence; with external or internal ophthalmoplegia, and with lid retraction or ptosis, either of which may be unilateral or bilateral. The lesions associated with it are pathologically varied and usually obscure. Chronic eneephalitis lethargiea, especially of the Parkinsonian type, has been responsible for a small number of eases. Several have high blood pressure; in a number of eases the exophthalmos has been associated with ophthalmoplegia and enlargement of the thyroid, although the relationship between the two is difficult to explain. Clinical signs and symptoms indicate that the lesion is usually in the midbrain."

I would like to ask Dr. Reese if he would be kind enough to explain the mechanism of exophthalmos seen occasionally in patients with hypertension where there is no evidence of hyper-

thyroidism.

Discussion: Walter S. Atkinson, M.D., Watertown, N. Y. I have very little of interest to add in the discussion of Dr. Reese's most interesting paper.

He was necessarily obliged to omit many of the causes of exophthalmos which unfortunately included the ones we see more commonly in Northern New York.

Being in the so-called goiter belt, we see quite a number of such cases with exophthalmos.

Also, as most everyone in our vicinity seems to have some sinus trouble, according to the nose and throat men, consequently there are a number who have orbital involvement with exophthalmos but this is not pertinent in discussing Dr. Reese's paper.

Again, Watertown is said to be in the eancer belt but in spite of the fact that we see a number of cancer cases very few of our patients seem to select the orbit as a site for their new-growth.

We do see a few angiomas of the orbit which cause exoplithalmos. In an infant aged 4 months, I made the diagnosis of a dermoid cyst. There was no increase in size of the tumor when the baby cried or the usual bluish color, and it seemed quite freely moveable. I thought there might be a process or ramification of the cyst extending deeply into the orbit to give rise to the slight exophthalmos.

Under local anaesthesia, the tumor was exposed and then it had the appearance of an angioma which with some difficulty was removed as it did extend quite deeply into the orbit.

On microscopic examinations by our pathologist, the State Institute here in Buffalo, Verhoeff and Friedenwald, the diagnosis varied from an adenocarcinoma of the lacrimal gland to an angioma. As the recovery was uneventful with no recurrence after two years, no doubt the diagnosis of angioma was correct.

About two years ago in Vienna, I saw 2 patient with a tumor which presented at the lower orbital margin temporally, pushing the eye, which was microphthalmie, up and nasally, and had the eye been of a normal size it no doubt would have been somewhat proptosed.

The tumor was quite freely moveable and the diagnosis on the hospital record was eyst and

micropthalmus.

At operation the suspected eyst did not shell out as anticipated but seemed to have a very substantial pedicle, which extended well back into the orbit.

On examination later, the eyst was considered a rudimentary eye. Possibly it was similar to the microphthalmic eye with retina lined cyst mentioned by Lang and Collins and the last two microscopic slides shown by Dr. Reese;

EXOPHTHALMOS, ITS SURGICAL TREATMENT*

By WEBB W. WEEKS, M.D., NEW YORK, N. Y.

OU have just listened to an explanation of the causes, the symptoms and the pathology of exophthalmos, unilateral and bilateral. Systemic or constitutional causes are taken care of by the internist. Encroachments upon the orbital cavity from the nasal sinuses are handled by the rhinologist. The neurologist and the neurological surgeon take care of conditions arising intracranially, producing an exophthalmos.

With your permission, I will limit my remarks

With your permission, I will limit my remarks regarding the treatment of exophthalmos in this article to a description of three surgical procedures, which take care of local conditions likely to be of serious danger to the usefulness of an eye.

Consideration will be limited to those cases in which the eyeball is displaced forward far enough to threaten serious pathological changes from a failure of eyelid closure. Temporary conditions arise, such as are seen in exophthalmic goitre cases where medical treatment is being carried out with the likelihood of a subsidence of the exophthalmos in the near future. Where the rhinologist exposes the ethmoid or frontal sinus by the external route, when an exploration of the orbit is made or when an orbital tumor is removed, the eyeball is pressed forward between the eyelids and exposed to injury. An ulcer of the cornea may result with subsequent loss of the eye.

To forestall these possible complications the exophthalmic goitre cases may be carried along by the use of oil drops during the day and an eye patch at night. The annoying diplopia may be at least temporarily relieved by the use of prisms or the wearing of a ground glass over one eye to exclude the vision of that eye. Failure to control the dangers of a lagophthalmos by this means, makes necessary a partial tarsorrhaphy. Either one central intermarginal adhesion or two lateral ones are made. These are allowed to remain until all danger of an ulcer is passed, the exophthalmos having subsided through medical treatment. The method of accomplishing this operative procedure is depicted by the following lantern slides.

Areas 4 mm. in length are marked out on the intermarginal portions of the upper and lower lid margins which touch each other when the lids are closed. The lid clamp is applied so as to include this area on first one lid, then the other. The mucocutaneous intermarginal area from the cilia follicles to the posterior lid margin is pierced to a depth of about ½ mm. The knife is carried from one end of the 4 mm. space marked out to the other and this piece of tissue excised. This exposed area is incised centrally to the depth of 2 mm., allowing the wound to spread when the lid margins are approximated by sutures.

A double armed suture on which a rubber pig

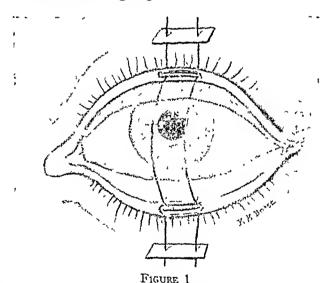

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

is threaded with needles attached, starts 2 mm. below the cilia, 3 m.m. apart, on the skin surface, running backward and upward through the thickness of the lid to emerge 3 mm. apart at the posterior part of the denuded area of the lower lid, entered at the posterior margin of the corresponding denuded area of the upper lid, similarly placed and spaced, to emerge through the skin of the upper lid, a similar distance above the cilia.

A rubber pig is threaded as before, and the suture tied snug enough to approximate and hold the denuded intermarginal areas included together, until healing takes place.

A small amount of Bichloride ointment is placed between the free lid margins and a light dressing is applied to both eyes.

The complications arising in carrying out this procedure are from placing the incision too near the cilia follicles injuring them, resulting in a loss of the cilia. Too deep an incision may lead to a deforming notch after adhesions are severed. Tying sutures too tightly may cause them to cut through. This holds more often where too shallow a bite is made and no rubber pigs used. The lid margin between tight sutures may be lost by necrosis and sloughing.

Shows a central intramarginal denudation with central incision and insertion of double arm suture with rubber pigs.

The sutures are left in five to eight days, the dressing on this eye about ten days. Adhesions are left intact until the purpose for which they were intended is accomplished—may be two to six months or more. In some cases these adhesions gradually stretch out through muscular effort to open the eyelids. They need not be cut for this reason as they still are of some aid in holding the eyelids together enough to prevent exposure of the cornea. Should a conjunctivitis

of a purificial nature set in, these adhesions may have to be cut carly although the usual secretions easily escape between the adhesions

Liamples

I 1 cmale, Age 53 Seen December 1, 1929 Complant —Sudden pain and swelling of the left eye

History —Negative except for present illness which began two dijs ago Subjective sensition of pulsations in the left eye since onset. Orbital prim, worse at night

Objective signs — Marked exophthalmos with swelling of eyelids and chemosis and congestion of the conjunctiva, left eye

Conhith-lunometer readings, O.D. 18, O.S. 26. Ocular movements ml. Failure of lids to close 3 m.m. Corner hazed with struning of the lower 1/3. Photophobra and te iring.

X-ray—Dense osseous mass filling left antrum apparently surrounding the optic foramen

Diagnosis —Osteoma of the left maxilla, in operable

Treatment -Anti Luctic

Operation —Partial tarsorrhaphy—two ad liesions

Result —Rehef of local irritative symptoms for four months when patient disappeared No change in exophthalmos noted

For operations during which the orbit is opened attended by possible exposure of the eyeball either at the time of the operation or subsequently, due to the congestive reaction following such procedures, similar sutures may be applied without interinarginal adhesions being made

For an exophthalmos likely to be permanent, a keratus from lagophthalmos threatening, with a very annoying irritative conjunctivities, necessitates the operative procedure of external tarsor rhaphy. Approximate amount of closure of the pulpible fissure can be determined by finger closure of varying degrees at the outer canthal ingle enough to insure closure when the patient is isleep. Many times it will amount to an insufficient closure not permitting of the effect desired and giving a disfiguring deformity. It is then necessary to enhance the tarsorrhaphy affect by means of the external canthal ligament reces-

The Fuch's tarsorrhaphy and a modification as developed by Dr. J. M. Wheeler is shown by the following lantern slides

A six to ten mm closure of the palpebral fissure inving been determined upon, a knife nick marks this distance off on the intermarginal space from the external eanthal angle misally, on both upper and lower cyclids

A Jaeger Lid Plate slightly smeared with Inchloride ointment at one end, is then inserted into the cul-de-sac at its external limit, first the lower Pressure backward on the other end of this plate holds the lid taut and brings into prom mence the intermarginal space The same pro cedure is carried out when the upper lid is to be operated upon The narrow knife now is inserted into the gray line and the lid split from the mark indicated, to the canthal angle. The splitting of the lid is carried to the depth of 4 mm from the masal end of the cut, the skin portion is cut through perpendicular to the lid margin for a depth of 4 mm The cilia follicles of this portion are excised to the external canthal angle

The Jaeger plate is inserted into the outer upper cul de sac. The lid is similarly split and a perpendicular cut made to the lid margins approximately 3 inm in depth. From the superior end of this cut a cut is made through the ciliary thickness of the lid obliquely outward and downward to the external canthal angle. This triangular shaped skin flap is excised.

The needles of a double armed suture are inserted 3 mm apart through conjunctiva and tarsus of the upper hid about 2 mm above tarsal lid margin. The needles and suture are carried through the skin flap of the lower hid from within outward 3 mm apart and 3 mm from the flap margin. The needles and suture are carried

through a rubber pig and tied, bringing the skin flap into the defect of the upper lid. The conjunctiva and tarsus of the upper lid slides over that of the lower lid.

Interrupted black silk sutures are then inserted approximating accurately the skin edges of flap and upper lid. One suture through the lower and nasally cut edge of the skin flap and the cut skin edge of the upper lid skin wound just above the cilia should be made insuring close approximation of the intermarginal fissure and a perfect canthal angle.

Bichloride ointment 1-5000 is applied to the lid

margins and a snug dressing applied.

Perforation of tarsal or skin flaps with the knife lead to granulations, imperfect healing and subsequent deformity. Faulty denudation of the upper lid or poorly shaped skin flap of the lower lid give poor adjustments and cause a deforming scar in healing. Too tight tying of the double armed suture, may cause death of the skin flap, nullifying the operation's object and producing a marked scar deformity.

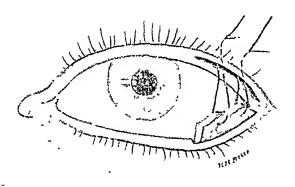

FIGURE 2

Shows the splitting of the upper lid, the isolation of the tarso-conjunctival flap and insertion of sutures which pull this flap into the split of the upper lid above.

Sutures are removed on the sixth or eighth day although a dressing should be kept on for ten days. Healing is usually uneventful. In cases where the effect from this operation is not all that is desired, but on pressure backward and outward over the external canthal ligament a closer approximation of the palpebral fissure occurs, a recession of the canthal ligament can be done.

A skin incision may be made following the curve of the orbit margin. The incision is deepened through orbicularis, septum orbitale and aponeurosis of the levator muscle and the flap

The canthal ligament thus exposed is freed from its insertion, caught in a double armed chronic gut suture and the point of attachment carried back behind the tubercle as far as necessary to accomplish the result desired, or the ligament may be resected and be reattached well back on the tubercle periosteum.

The septum orbitale should be sutured with plain catgut and interrupted sutures to its original attachment to periosteum at the orbital

The skin closure is made by interrupted black silk sutures. Dressing should be applied with firm even pressure to prevent hemorrhage and

congestive swelling.

Some scarring may result from the lid incisions, too narrow tendon flaps do not hold and infection from the gut suture may take place. Where the orbicularis muscle flaps are used instead of the canthal ligament, they tend to stretch out giving a partial result.

Healing is usually uneventful. The skin suture is removed on the fifth day. The result desired as an adjunct to the external tarsorrhaphy is ex-

External Tarsorrhaphy Fuchs: Lehrb d Aughlk, (10), Win, Denticke Hale: Klin Mbl f Aughlk, 42, 1, S 577. Elsching: Zschr f Aughlk, 33, S 280. Wheeler, J M: Arch of Ophth, 1924, Vol 53, p 76

Discussion. Harry M. Weed, M.D., Buffalo, N. Y.; Dr. Weeks has so well covered the local

treatment of exophthalmos that very little remains to be said without going outside the field of this paper

I would like to stress the making of two partial tarsorrhaphys one over the inner margin of the cornea and the other over the outer. One does not know when resorting to this procedure whether the cornea will require protection for a

Median Tarsorrhaphy Panas: Traite des Maladies des Yeux, Zome II, 1894, 137. Van Lint: Arch d'Ophth, 46,411, (July) 1929

few days or weeks or a much longer time. With the two intermarginal adhesions so placed it is quite possible for the patient to have useful and comfortable vision for an indefinite period looking out between the two adhesions which stretch out to a moderate degree.

And here I wish to call attention to the fact that in Graves disease exophthalmos to an alarming extent may appear months after the apparent surgical cure of the disease. It seems to be the

general belief that the exophthalmos is the result of the toxicity of hyperthyroidism; if there is no toxicity there likewise is no exophthalmos. But notwithstanding this dictum and the expectation that surgical cure of the disease will be followed by disappearance of the eye signs and symptoms in milder forms and improvement in the more» severe ones, it nevertheless is true in a considerable number of cases that after a more or less complete thyroidectomy followed by relief and apparent cure of all symptoms, exophthalmos and other eye signs characteristic of this disease may make their appearance months later. Associated dysfunction of other ductless glands does not entirely explain this picture. We therefore must stand ready to treat this form of exophthalmos along the lines which Dr. Weeks has suggested long after the disease seems to have been cured.

Case: Mrs. B. D. W., age 47, first seen 5 years ago. Examined for refraction, moderate error and normal corrected vision. Eyes otherwise

O.K. Some months later symptoms of Graves disease gradually appeared without exophthalmos and thyroidectomy was performed with apparent cure of all symptoms. Six months later exophthalmos gradually developed with marked retraction of upper lids and the usually associated signs plus diplopia: parcsis of left superior rectus muscle. The diplopia persisted for more than a year then gradually disappeared but the exophthalmos is still present to a marked degree. Local treatment with no surgery, and covering one eye during most of the period of double vision was all that was required.

Just one other suggestion—external canthotomy will give all the relief required in some cases of temporary exophthalmos which threatens the integrity of the cornea. Chief of these are those resulting from severe orbital hemorrhage—and orbital cellulitis. This is a simple procedure and one that probably should be employed much more

often than it is.

Discussion: Dr. John F. Gipner, Rochester, N. Y. The operative technics of partial tarsorrhaphy, the Fuchs' tarsorrhaphy and a modification of the latter developed by Wheeler have been most ably described and illustrated by Dr. Weeks. If one wishes to save the cilia of the lid margins the Elschnig tarsorrhaphy is advisable. I should like to stress a point mentioned by Dr. Weeks, viz., the importance of suturing the lids together preliminary to any exploratory operation of the orbit whether one employs the Kroenlein or the brow incision route. If the lids are not sutured, the displacement of the orbital contents when the exploring, palpating finger is inserted into the wound, causes protrusion of the globe through the open lids with consequent corneal damage.

From my experience in observing the eyes of many exophthalmic goitre cases at the Mayo Clinic I would say that ophthalmic surgical relief is rarely required. Operations which narrow the palpebral fissure or in addition retroplace the external palpebral ligament have little effect in reducing exophthalmos. It would be a great advance in ophthalmic therapeutics if some medical or surgical procedure could be devised which would reduce the exophthalmos in those cases of hyperthyroidism where the exophthalmos persists in spite of thyroidectomy and medical treatment. Perhaps Naffziger's orbital decompression operation is the answer to this need.

There is a form of severe exophthalmos that follows thyroidectomy which fortunately is rarely seen. It develops rapidly after removal of the gland and is not associated with hyperthyroidism as measured by clinical signs and the basal metabolic rate. No satisfactory explanation for this phenomenon has been advanced. Plummer thinks it is due to the secretion of an inferior thyroid product. It is usually bilateral and is character-

ized by a tense edematous swelling within the orbits and rapid protrusion of the globes between the lids. The onset is so rapid and the edema of the orbit so firm that the eyeballs become fixed. the ocular conjunctiva becomes chemotic protruding between the lids so that they can not be To relieve the tension of the lids canthotomy may be performed but it affords little relief. Canthoplasty is impossible. must be treated with oil and an air-right Buller's shield until the acute stage subsides after which motility of the globe and exibility of the lids re-These cases : . . . distressing problem in as much as there is no way of predicting who will develop this condition and it may appear in hyperthyroid patients who previous to thyroidectomy had little or no exophthalmos. Up to the present time in spite of the most careful protective treatment many of these eyes have been destroyed,

Howard C. Naffziger of the University of California performs orbital decompression on these cases. Through the transfrontal route the anterior cranial fossa is opened and after dissecting up the dura, the roof of the orbit is removed The decompression opening is extended backwards to include the roofs of the optic foramen and the superior orbital fissure. The zonule of Zinn at the apex of the muscle cone is split. These measures are performed to free any possible constriction to the veinous circulatory outflow from the orbit. Naffziger finds the extraocular muscles greatly enlarged, not from hypertrophy but due to muscle swelling from edema and fibrosis. He reported his results from eight such operations at the A. M. A. convention at New Orleans this month. In a case reported in the Trans. of the Am. Surg. Assoc. last year he reduced the exophthalmos in a patient 9 m.m. by this operative procedure.

Discussion Martin B Tinker, MD, Ithaca, N Y-The papers in this symposium have been most interesting and instructive. The paper by Dr Reese seemed to me of unusual scientific Dr. Gipner in his discussion has mentioned the work of Dr Howard Naffziger of San Francisco in the treatment of extreme exophthalmos from gotter I heard Dr Naffziger's original paper at the meeting of the American Surgical Association it seems to offer a definite source of relief in certain advanced cases. Certain types of exophthalmos offer difficulties which are of spccial interest to those of us who have to do with large numbers of gotter Experience in over 5 000 cases of gotter during 27 years leads me to believe that surgery for exophthalmos should be resorted to only in extreme cases and usually after they have been kept under observation for a considerable period of time. I have seen disfiguring exophthalmos exist for over five years after the gotter had been removed and then disappear entirely without any special treatment. It is usually the last of the characteristic symptoms of goiter to disappear. The most important considerations are disfigurement, pain, and danger of loss of the eye, the last two occasionally demand mg some radical operation for relief Several years ago I presented before the Oplithalmolog ical section of the American Medical Association a method of approach in the radical operation having for its eluef advantage that the filaments of the facial nerve were not divided. It seemed to me that this might be of interest to this section in connection with this discussion. A study of 25 dissections of the face by students at Cornell Medical College in Ithaca showed a distribution of the facial nerve such that the incision could be placed in the eyebrow, continuing downward and outward along the upper border of the zygoma without injuring important filaments of the facial nerve in any case and injuring iminportant filaments in only a very few cases. This offers a great advantage over the old musion proposed by Kronlein as shown by Bockenheimer (Arch f klin Chir 1904 LXXII) Kocher urged the danger of the Kronlein incision and quoted statistics of 120 cases with injury to the facial nerve in a very large proportion

CLINICAL PICTURE OF UNILATERAL INFARCTION OF THE MEDULLA By EDWARD LIVINGSTON HUNT, MD. and GORDON H GRANT, MD, NEW YORK, N Y

from St. Luke's Hospital New York, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932

INTRACRANIAL occlusions are common; they are responsible for a certain percentage of transitory somatic paralyses and, to a lesser extent, for the deaths of the apopletic type. A review of the literature indicates, however, that the lesion does not commonly occur in the region here described. The following case is of interest for two reasons, first, because the lesion produced definite localizing signs, and second, because it masked physical signs of a serious intra abdominal condition.

This patient was a seventy-year-old clergyman, a mild diabetic, who, for two days, had suffered from a severe headache, and for several months, from dispinoea on evertion and repeated attacks of vertigo. The day before admission the vertigo became so severe that he collapsed and went to bed. The next morning he awoke with projectile vomiting and at once realized that he had difficulty in speaking and swallowing and temporarily saw double. The difficulty in speaking and swallowing made him so helpless that he was obliged to come to St. Luke's Hospital in New York, where he

remained without improving until his death, eighteen days later.

On admission the patient was hoarse and had difficulty in breathing and swallowing. The left pupil, larger than the right, was sluggish, the right was immobile and both were irregular. There was no nystagmus. There was an intermittent slight facial ass immetry. The right vocal cord was motionless in the midline, the left moved freely. The tongue deviated to the right and tendon reflexes were normal. Babinish's sign was present on both sides. There was slight dismetria in the right arm and leg.

On the left side of the body there was complete loss of prin and temperature sense, up to, and including the ear, but not in the area supplied by the trigeminal nerve. Touch was normal throughout

Moist rales and diminished breath sounds were heard over the bases of both lungs

The heart was enlarged to the left The aortic second sound was ringing. The pulse was 105, the rhythm being interrupted by extrasys-

toles every fourth beat. The radial arteries were thickened. The blood pressure was 139/90.

Abdominal examination, apart from flatness in

the flanks on percussion, was normal.

Urinalysis showed faint traces of sugar, albu-

min, and acetone.

Blood examination showed 98 per cent hemoglobin, 5,400,000 red cells, and 11,900 leucocytes per cubic millimeter. The blood sugar was 2.85 per cent, urea nitrogen 15.7 and the carbon dioxide combining power 50.4 volumes per eent. The Wassermann test was negative.

The diagnosis was: Thrombosis of the pos-

terior cerebellar artery.

Progress: The patient showed no improvement during his stay in the hospital. His blood pressure on the day following admission was 200/100, but dropped to 146/100 and remained there until The leucocyte count shortly before death was 20,000 per cubic millimeter, with 92 per cent polymorphonuclears. The high temperature, leucocyte count, and chest findings suggested a complicating broneho-pneumonia. On the twelfth day the temperature and pulse began to rise and six days later he died with a temperature of 108.

The autopsy made by Dr. Gordon H. Grant,

The pupils were equal and there was no strabismus. The lungs were air containing throughout, showing only slight eongestion at the bases. The heart was enlarged weighing 570 gm. coronary arteries showed extensive atheromatous change, but were patent. The aorta presented moderate atheromatous change, but no ulceration.

The gall bladder lay deeply embedded in the substance of the liver. It was very large, the surface brown and granular, and the viscus tense. The cavity contained a few small black stones and a large amount of foul-smelling black fluid mate-The walls were very much thickened and the mucosa showed large irregular areas of gangrene. The hepatic and common ducts were normal. There were many adhesions above the fossa vesicalis, but the peritoneum was glistening and free from exudate.

The cerebrospinal fluid was increased. brain weighed 1470 gm. and was softer than usual. The medulla oblongata, in the right pyramidoolivary region, presented a small oblong area of softening, paler than the surrounding tissues, except at its margins, where it was slightly hemorrhagic. The area measured approximately 7 mm. in length and 5 mm. in diameter. The pyramidoolivary groove was flattened at the point of emergence of the right hypoglossal nerve, that of the right vagus being also slightly involved. cerebellum was very soft with no appreciable difference on the two sides. No areas of softening or hemorrhage could be found elsewhere in the brain substance. The proximal portion of the posterior inferior cerebellar artery showed neither thrombotic nor embolic process. Its smaller

branches were embedded in the medullary substance and were examined in the sections.

Microscopic cross-section of the medulla at the point of emergence of the vagus and hypoglossal nerve showed an irregular area of infarction extending along the right lateral border of the medulla from the middle of the restiform body superiorly to the pyramido-olivary groove ventrally. Medially the process extends to the middle of the olivary nucleus and sends an oblique prolongation upward to the region of the hypoglossal and vagus nuclei. The process is essentially one of anemic infarction, showing necrosis of blood vessels as well as of the nervous tissue, producing a rarefied zone in which the nuclei are in various stages of degeneration, and all the structures are progressively degenerated toward the center of the infarcted area. There are practically no infiltrating polynuclear cells, but a few collections of lymphocytes are occasionally seen, and a zone of congestion and hemorrhage exists around the terminal vessels. This closely follows the outline of the olivary nucleus over most of its extent but is not entirely limited to it. extensive fatty and cystic degeneration. ganglion cells show granular degeneraion, swelling and loss of their nuclei; almost none of them retaining their normal outlines. Amyloid bodies are very numerous throughout not only the medulla but also the remainder of the brain tissue. The blood vessels of the meninges in this region are relatively normal. The veins contain no emboli, nor are they especially thickened. The remainder of the brain shows no lesions; neither meninges nor eerebrum appear involved.

This is obviously a localized degenerative process in which acute infection has undoubtedly played a part, but the absence of septic lesions in the remainder of the brain shows that the blood vessel involved is limited to this portion of the

Suppurative changes have not taken place, and therefore it is suggested that the vascular lesion is the result of an aseptic thrombus, as the degeneration is clearly of a duration long enough to have given rise to suppuration had there been any general blood stream infection.

Sections of the gall bladder show a gangrenous process localized to portions of the wall, with an

active infection in the remainder.

The cardiac muscle shows extreme degenerative and productive myositis. The fibers have been hypertrophied, show secondary atrophy, and large areas of fibrosis in which no muscle fibers remain.

In the lungs are small areas of bronchopneu-

monia; in the vessels septic thrombi.

The spleen shows the changes due to sepsis. The clinical signs and symptoms with one exception, are well explained by the position and extent of the medullary lesion. The exception is the interference with the light reflex in the pupils. There is no anatomical basis for belief that the motor supply of the ciliary muscle was interfered

with by the lesion

The interception of the impulses of the hypoglossal, vagus and glosso pharyngeal nerves were demonstrated by the unilateral motor paralysis of the tongue, the paralysis of the right vocal cord with hourseness, the tachycardia and the difficulty in swallowing The vertigo at the beginning of the illness was probably due to the close proximity to the area of infarction of the descending root of the vestibular division of the acoustic nerve and the transitory facial asymmetry to the close proximity to the lesion of the nucleus of the facial nerve. There was nothing to indicate involvement of any of the cranial nerves cephalad to the facial. There was no skeletal paralysis, the lesion had not included the pyramidal tract, it occurred above the decussation

The dysmetria of the extremities of the right side was undoubtedly due to the destruction of the arcuste and cerebello olivary fibers in the right side of the medulla. If further tests had been made, it is probable that more extensive loss of cerebellar control would have been demonstrated

The loss of the sense of pain, heat and cold on the contralateral side of the body is explained by the impinging of the infarct on the right inedial lemniscus The lemnisci decussate just medial lemniscus below the area of infarction and the fibers carryme the sensation of touch were not affected

Explanation of the projectile voiniting must, at best, be a matter of conjecture Vomiting is a common symptom in intracranial pressure, and such may be the explanation of this case. It is also possible, that the vomiting was a direct re suit of the lesion being in the medulla

A man of seventy who, on admis sion to the hospital, presented a syndrome characterized by various motor and sensory nervous phenomena, of a few hours' duration. A dingnosis of a viscular thrombosis in the mid portion of the right side of the medula oblongata was substantiated at autopsy

ARTIFICIAL LIGHT IN TUBERCULOSIS*

By GEORGE G MARTIN, MD, BUFFALO, NY.

F OR the purpose of this discussion a useful classification of light sources into three groups can be made

I hose sources radiating a high intensity of the ultra violet portion of the spectrum with a relatively low percentage of visible and infra-red The common source of this type wave lengths

is the mercury vapor are in quartz Those sources radiating a moderate intensity of ultra violet but having a high intensity in both the visible and infra-red range of the This group gives us, physically, our nearest artificial approach to sunlight. It includes the better carbon arc lamps and the General Electric Sun lamp

TlurdThose sources emitting a negligible per centage of ultra violet but having a high intensity of the visible and infra red portions of the spec-This includes ordinary types of Tungsten filament, carbon filament, and infra red apparatus Many of the carbon arc lamps on the market prop-

erly belong in this group

The above three groups are distinct and a phytions of sources from groups one and three which will give a radiation falling within group two It is sometimes important for a physician with limited equipment to remember this fact has a good mercury vapor lump, he can, with a small additional outlay, secure a good source of the group three type. With this he is able to make

sician using the lamp should know in which group his lamp belongs It is possible to make combina The selection of these patients suitable for arti

ficial light treatment is not easy. Patients with advanced pulmonary tuberculosis do not, as a rule show any appreciable improvement. The degree of toxemia appears to be as important a consideration as the extent of the lesion, at times it appears to be more so. With a few exceptions which will be discussed later, patients with advanced disease and evidence of toxenna are not given radiation There is a rare patient with advanced tuberculosis

combinations which will give him radiations falling in each of the above three groups

In the treatment of tuberculosis we have found that radiation from each of the above three groups is valuable. For practical purposes, however, the different types and makes of apparatus coming within each of the above groups may be used to meet the indications for the group with satisfac tory results. We may have our personal prefer ences and may be able to obtain better results with a given type of apparatus Physically, and ther apentically, it is difficult to offer proof that this preference is based on more than our familiarity with the use of the particular apparatus. Some change in technique may be necessary in making a change of apparatus No two lamps even of the same make and type, emit exactly the same radia

For this reason the indications for the selection of the source of light will be given with the understanding that substitution of equipment within each group may be made

Chronic pulmonary tuberculosis in adults

^{*}Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y May 25 1932

but showing little or no evidence of toxemia, in whom a trial with light therapy is indicated. Some of them will show improvement but many will have to be discontinued after a brief trial.

Patients in this group with extra pulmonary complications are given radiation more frequently. Even in the presence of moderate toxemia they are given treatment to secure an improvement of their complication. If given carefully, this improvement may be secured without ill-effects so far as the pulmonary condition is concerned.

Great care must be given in the radiation of any tuberculous patients and particularly those with an advanced lesion. Fatigue is easily produced. The effort involved in artificial light therapy, is not sufficiently appreciated. The end result of treatment is frequently harmful because this point is overlooked. If facilities are available for treatment at the bedside, it is possible to give light a trial when it would otherwise be contra-indicated. Transportation of patients, even within a hospital, involves considerable effort on the part of the patient. Transportation to and from a physician's office involves considerably more effort. value of light in the treatment of pulmonary tuberculosis is not sufficiently definite to warrant fatigue. Patients should be sufficiently observed before and after a treatment to estimate the amount of fatigue which has resulted. If there is evidence of fatigue, means must be taken to reduce the effort, and if this is not possible, the treatment should be discontinued.

The importance of fatigue in this connection is not overlooked as frequently as it was ten years ago. There are many physicians using light therapy at present who do not seem to appreciate that the fatigue is doing their patients more harm than the light could ever possibly do good.

In patients with moderately advanced pulmonary tuberculosis a relatively higher percentage is suitable for radiation. The percentage is still small and the degree of toxemia is again a very important factor in selection.

Of the group selected many will have to be discontinued. Evidence of increasing toxemia as noted by an increase in pulse rate, fever, irritability, headache, etc. is to be looked for. Progress, in the lung lesion, is unfavorable. If evidence of either one or both of the above is noted, it is usually desirable to discontinue treatment.

In incipient tuberculosis our results have been more favorable. Toxemia of any degree is again a contra-indication for treatment. All other patients in this group who, on admission, or after a period of rest, are in a good general condition, are considered suitable for a trial with light therapy.

The evaluation of the results obtained in the treatment of pulmonary tuberculosis is difficult. This is probably the reason for the widely different viewpoints expressed in the literature on the subject. All of our patients receive other indicated therapeutic measures. We have not felt

that the withholding of these measures in an attempt to evaluate the results of radiation was justifiable.

In carefully selected and carefully observed patients definite improvement has been noted. Many of the patients, at first selected, were discontinued after a relatively short period of radiation. Radiation has never been used as a routine for pulmonary tuberculosis. The possible advantages of this are to be considered. Tuberculosis is a long drawn-out confining disease. The usual exposure to natural light does not occur as it would in a healthy individual. Harmful results from carefully graduated, small dosage has been observed too frequently to allow of its routine use.

Improvement is to be noted in selected patients in regard to the amount of rest which they obtain. The sedative effect of ultra-violet light is well known. The exact mechanism of its action is not important for this discussion. The added rest and improvement in patients' mental attitude are important. An improvement in the appetite with a gain in weight in individuals who are below par is frequently noted. Subjective improvement appears to be more noticeable than objective. first a slight increase in moisture may be noted. This should be temporary, and should be followed by a decrease. If it is persistent, it is considered unfavorable. In many patients no objective changes in the chest findings are noted. The subjective improvement is considered of sufficient importance to warrant the expense and trouble involved in treatment.

In the selection of the source of artificial light it is our impression that a high intensity of visible and infra-red light is undesirable. These wave lengths have a heating effect. Many patients will tolerate them. Many observers have found that some patients with pulmonary tuberculosis will show improvement from exposure to sunlight. The same patients will tolerate the added heat, and can be given light from group two. There is a considerably larger group in which group one is tolerated. In doubtful cases a selection of the source from group one is more desirable. have used different makes of mercury vapor lamp for this purpose. The addition of heat has appeared to increase the toxemia. It has also increased the chest findings, more moisture and expectoration have been noted. Many patients have been seen who will tolerate the mercury vapor lamp, but will not tolerate the carbon arc, or the addition of radiant heat and light to the mercury vapor. Our experience with the General Electric sunlamp has been too short to permit of an opinion. It has many points of convenience in operation, and we are giving it a trial at the present

The Buffalo City Hospital has had to rely on artificial light for treatment. Sunlight has not been a dependable source for more than two or three months of the year. A comparison of nat-

ural and artificial sources has not been possible. This is probably the experience of most institu-

tions situated within the city limits

In review, artificial light particularly from the mercury vapor sources, is useful for a carefully selected group of patients with chronic pulmonary inherculosis. It is not recommended as a routine treatment. Patigue must be avoided if the treatment is to be beneficial. Radiation from group two sources is applicable for a smaller group of patients. Patients given radiation should be kept under observation and if evidence of in mercase in toccinia or more than a temporary increase in local chest findings is noted the exposure should be discontinued.

Considerable has been written of the treatment of the complications of pulmonary tuberculosis with light. Unterities is a complication which has The results have not been so been discussed favorable as the early literature would indicate Improvement has been noted in many when the chest condition has not been too severe with light therapy is given to many patients with enteritis in which the pulmonary condition, itself would not warrant radiation. A definite percentage of these show improvement of the enteritis without any ill effect on the lung condition Our results in advanced pulmonary tuberculosis with enteritis have been very disappointing. We have used general radiation with the addition of local radiation to the abdomen - The local radiation has been given just short of and up to a first degree ery thema

Larungeal involvement has also been treated Our indication and results have been about the same as for enteritis. It is of value particularly when the cliest condition is moderately advanced Symptomatic relief is considerable. Occasionally apparent healing has been noted. We have used general radiation with the addition of local radiation through a quartz applicator attached to a water cooled hup. It must be remembered that the epiglottis is a relatively avascular structure The dosage must be kept low if irritation is to be A little reaction is desirable but this should be kept at a nummum. If it is too great irritation with cough etc is produced. This defeats the purpose of rest. Lamps vary greatly in their efficiency With a new burner, between 15 to 45 seconds is the useful initial dose an increase with each subsequent treatment is given. Treatments every other day have given as good results as daily treatment. We have not noted any ini provement in rapidly advancing pulmonary dis-The results do not warrant the effort of the treatment for this particular type of patient

Pulmonary tuberculosis in children

When there is definite involvement of the lung parenchyma the above considerations are applied ble Children as a class show a better response than adults to light When the lesion is largely confined to the fulus nodes the condition is more satisfactory for treatment. Tuberculosis of all lymphatic nodes responds to light therapy. The results are satisfactory in children showing a fulus node enlargement both in those with tuberculosis as a definitely established citological agent, and those in which it can only be suspected. The treatment for both types is essentially the same

We have found involvement of the lymphatic nodes more frequently in children than in adults It is not rare in adults. The common sites of in volvement are the lulus cervical and axillary

node

Radiation from group two sources has given the best result. General radiation with a suberythema dosage is indicated. Sunlight is preferable when it is ditainable. Artificial light gives satisfactory results. An increase in the distance and time is more desirable than a short treatment. In accessible areas of the body the addition of a local first degree crythem i over a considerable area of surrounding skin is desirable.

The majority of these conditions subside in a satisfactory with Recurrence is seen if the treatment is not continued for a few months after apparent healing is noted. Treatment is indicated during the winter months of the following year for severe cases. If suppuration of accessible nodes does occur aspiration is used. The addition of thirty minutes exposure to a comfortable intensity of radiant heat and light will hasten the suppurative process and make aspiration easier. Unsightly scars due to surgical interference are avoided. The addition of x ray is sometimes an advantage. Surgical interior is seldom necessary. Involvement of the pleural and personal cavities.

The membrane of these cavities is closely allied in structure. They both become the site of tuberenlous involvement at times. Artificial light therapy is valuable in the treatment. The principles of its application are the same for both peritoncal tuberculosis and tuberculosis of the pleura Gen eral radiation from group two sources with a suber thema dosage is indicated. If the amount of fluid is excessive, the addition of a thirty to forty minutes local exposure with group three is an advantage Treatment should be commenced It is not necessary to wait until the temperature has completely subsided The majority of these patients make a good recovery erease of the fluid may be noted for the first few days but need not cause alarm. Aspiration except for diagnosis is rarely necessary Resolution occurs more rapidly and the amount of residual thickening is reduced to a minimum. In minipatients with a severe pleurisy with effusion no trace of the condition can be found a year later If there is much evidence of involvement of the ling parenchyma with the pleurisy or if there is little tendency to fluid formation in the peritoneal civity the addition of the group three as noted

above, must be made carefully. It is not always contra-indicated.

Satisfactory results have been obtained with chronic fibrous pleurisy under the same regimen.

Bone and joint tuberculosis

The results in this condition are sufficiently well known, to require no discussion. We have not been able to obtain the remarkable development of muscle and the increase in muscle tone which is noted under natural light. This is a valuable feature of light treatment, and it makes the results obtained with artificial light distinctly inferior to those obtained with heliotherapy. A combination of light therapy and surgical treatment is indicated and is usually possible. Good results can be obtained in this condition with general radiation without local exposure. A spirit of cooperation between the physical ther-

apeutist and the orthopedic surgeon will secure better results than an antagonistic attitude. More attention should be given to the necessary details which allow both methods of treatment to be carried out concurrently than to relative value of the two methods of treatment if used separately.

Genito-urinary tuberculosis

A few patients with genito-urinary tuberculosis are admitted to the Buffalo City Hospital every year. We have used light from group two sources and while the number of patients actually treated is not large, the results obtained are in agreement with other observers. It is a valuable adjunct to treatment. It does not replace surgical treatment when this is feasible. The results to date warrant continuation of its use as a supplement to surgical treatment and in inoperable cases. An occasional surprisingly good result is obtained.

SUPERSPECIALIZATION IN NEUROPSYCHIATRY

By IRVING J. SANDS, M.D., BROOKLYN, N. Y.

Chairman's Address before the Sections on Neurology and Psychiatry, at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

HE duty of the medical profession is to prolong life and to relieve human suffering. Such suffering may result from physical or psychic causes. In order adequately to perform their duties, medical men must not only acquaint themselves with the fundamental facts concerning the different diseases and the best methods of treating these disorders, but they must also seek for new truths that may enable them to discover new causes of illness and more adequate means of treatment. Furthermore, it is the duty of physicians to train properly qualified men to treat the sick. Moreover, they have the additional task of preventing illness whenever possible. Hence, we have in medicine several subdivisions, namely, therapeutics, research, teaching, and preventive medicine.

Human behavior is the resultant of several factors, the most important of which are the physical, intellectual, instinctive and emotional ones. Of the physical factors, the nervous system and the endocrines play the dominant roles. Defective intelligence leads to mental deficiency. Instinctual and emotional disorders lead to the psychoneuroses, many of the psychoses, delinquency, and general maladjustment.

Neurology concerns itself with disorders due to physical and chemical changes in the nervous system. Neurologists have for years concerned themselves not only with neurological medicine, but also with behavior disorders for which no structural alteration in the nervous system could be established. Psy-

chiatry, in its broadest sense, deals with all forms of abnormal behavior. While it is generally regarded as primarily concerned with the psychoses, it has been dealing with the psychoneuroses, mental deficiency, criminality and delinquency, and with general maladjustment

Neurology and psychiatry have been regarded as independent specialties, each with its own peculiar interests, and requiring different training and preparation for those physicians who might later follow the particular specialty. However, it has been found that the field of interest of the two specialties are not clearly demarcated and frequently overlap. In fact, many of the better types of neurologists and psychiatrists have long realized a basic unity in the two specialties, and have hoped for the union of the two into a common specialty. The World War fulfilled this hope, and created the specialty of Neuropsychiatry. The fundamental unity of neurology and psychiatry became quite apparent in dealing with the large number of neurological and psychiatric disorders encountered amongst the troops, and the neuropsychiatric division in the medical corps was established as the most logical and feasible method of treating them. A similar division exists in the Veterans' Civilian hospitals, in response to their own particular needs, have established neuropsychiatric wards and outpatient departments. The specialty of neuropsychiatry has thus become a reality.

Specialization is a natural development in

modern civilization. It is found in every field of human endeavor. Its aim is efficiency and perfection. Specialization in neuropsychiatry may be best achieved after a general hospital training or several years of general medical practice, followed by special studies in neuro-anatomy, neuropathology, and medical psychology, with intensive training in clinical neurology, psychiatry, psychoneuroses, mental deficiency, delinquency, and, if I may add, psychoanalysis

Neuronsychiatry is therefore a large specialty embracing amongst others such subdivisions as neurology, jisychiatry, psychonenroses, delinquency, child guidance, mental hygione montal deliciency and general maladjustment Because of the very breadth of this specialty, it is natural to expect that some neuropsychiatrists may devote most of their time to one or two subdivisions, such as psychoanalysis, clinical neurology, child guidance. Nevertheless, by virtue of their training and experience, they are competent to recognize and diagnose and even treat all other subdivisions of neuropsychiatry. When they meet cases which fall in subdivisions other than those in which they have special interest, they are able to refer these cases to other competent physicians for proper therapy

In recent years there has been an increasing tendency towards superspecialization in neuropsychiatry By superspecialization I mean the limitation of one's activities to some one subdivision of neuropsychiatry without any previous adequate training in the other subdivisions | Frequently these superspecialists lack even a general hospital internship training, or a general medical practice experience This tendency to superspecialization is due in part to the unique mental make-up of the superspecialist partly to the trend of some medical schools to encourage and foster a so called research spirit in third and fourth year medical students, and partly to the peculiar psychology that has dominated the post-war decade now fairly common for recent medical graduates to enter into clinical neurology, psychoanalysis, child guidance psychiatry, etc., without any previous fundamental training or experience in basic allied subjects

Superspecialization has certain advantages in that it enables one to devote his entire energy in training and research in one particular disorder. It occasionally leads to new discoveries. It carries with it the rewards that accrue as a result of intensive application to a small and limited field. Medical schools en courage superspecialization as it stimulates research and arouses enthusiasm in students. The superspecialist may prove to be somewhat of a showman, and may invite endowments to

various departments in the school. The patient, in the hands of the properly selected superspecialist, receives most expert care. The superspecialist often establishes a well merited reputation, and is in the eye of both the profession and the laity. Superspecialization, therefore, has a definite place in neuropsychiatry, and, when practiced by modest men who are cognizant of their limitations, is extremely productive of excellent results to all concerned.

Superspecialization has its definite drawbacks. It tends to create a feeling of omnipotence and even intolerance in those who practice it I have heard the dcan of a leading medical school in New York City say that he has found a tendency on the part of the full time teachers attached to his school to look down upon the part time men, and to disparage their work. It often leads to misunderstanding and to unwarranted criticism The prevention of nervous and mental diseases has been called a myth, and child guidance clinics an effrontery. It leads to conflicting opinions that tend to shake the confidence of laymen in the medical profession At a recent trial the professor of psychiatry in a leading medical school and the superinten dent of a State Hospital both declared the defendent to be suffering from the manic phase of manie depressive psychosis, while an eminent neurologist, who has a well merited reputation in his particular field, declared the patient to be of sound mind. Many of the sol diers who had suffered traumatic encephalo pathic conditions in the war, were diagnosed as livsterical and their troubles as psychogenic ın nature Many neurologists and even psychiatrists still decry the psychoanalytic movement without making the least effort to understand its basic principles. It occasionally leads to unwarranted claims at cures. The claims of some endocrinologists many of whom sit in the councils of the medically select are both unscientific and contrary to facts

The neuropsychiatric patient is often in a quandary to whom to turn for help. He knows neither the nature of his own ailment nor the special field in which each superspecialist is To him they are all "nerve most proficient specialists" It is therefore not uncommon for the patient to seek help from those who are not competent to treat his illness. The super specialist is often in no position to correctly diagnose the patient's neuropsychiatric disorder The early manifestations of such diverse conditions as cerebral arteriosclerosis, cerebral neoplasin, and some of the psychoneuroses may be identical. A superspecialist in clinical nenrology proudly told me of his ingenious method of treating a patient suffering from an auxicty

neurosis. She had attributed her illness to having eaten some meat which had lodged in her throat and had blocked her stomach. He immediately put the patient under a mild ether narcosis, and when she regained consciousness, produced a piece of meat which, he told her he had removed from her stomach. A superspecialist in psychoanalysis, most competent in his own limited field, was treating a young woman for a neurosis, but, to be fair, not in the orthodox and accepted psychoanalytic technic. When two days before her death from an obvious cerebral disease, it was suggested to him that she might be suffering from an organic brain lesion and most likely from a neoplasm, he scoffed at the suggestion.

The attitude of medical schools in encouraging research is most commendable. However, it should be restricted to those who show special inclinations in that direction, and should not be universally applied to all students. It would seem advisable to have a complementary tendency in medical schools to encourage the students to obtain a general and thorough medical training, and later an adequate special training if they were contemplating entering a specialty. This latter tendency would be applicable and beneficial to a very large number of students, and would prove of greatest benefit to a large number of patients. Medical students are often left in a most confused mental state after listening to some superspecialists; they surely fail to get the proper perspective of the subject. It would therefore seem advisable that in those medical schools where the various subdivisions of neuropsychiatry are taught by superspecialists, that a course be given by a competent neuropsychiatrist in order to orient the student in the proper evaluation of the general field of neuropsychiatry,

The superspecialist is always at the mercy of his own limited and restricted specialty; in his own circumscribed field he is expert, but outside of it he is helpless. If modest and cognizant of his own limitations, he is most productive and highly valuable, otherwise he may become dangerous. He must constantly consult his medical colleagues whenever he is treating any patient.

One often hears rather discordant notes in modern trends in medical teaching. Neurologists and psychiatrists alike preach the necessity for treating the patient as a whole, and for an understanding of the totality of the patient's reaction as an indispensable prerequisite in instituting adequate therapy. And yet there is the opposing trend of urging recent medical graduates to spend all their time on some one problem, which leads eventually to superspecialization. How a superspecialist can possibly understand the totality of the patient's behavior is indeed puzzling to me. A large number of the superspecialists are full time institutional men or occupy full time teaching positions. It is highly problematical whether

such sheltered and exclusive environments are conducive to an understanding of the totality of the patient's behavior in an entirely different environment.

The neuropsychiatrist on the other hand, by virtue of his broad training and experience, is able to diagnose the various subdivisions of neuropsychiatry. He is better equipped than is the superspecialist to manage the patient as a whole. When the neuropsychiatrist limits his work to one subdivision of neuropsychiatry, he is less apt to fall into the pitfalls that confront the superspecialist. As a teacher, the neuropsychiatrist is more likely to give the student the proper perspective of the special subdivision which he may be teaching, even though he may be lacking the extreme enthusiasm of the superspecialist. In the field of preventive neuropsychiatry, the neuropsychiatrist is particularly fitted to appraise the various factors that may contribute to the person's disorders.

Conclusions

1. Neuropsychiatry is a broad specialty and embraces such subdivisions as neurology, psychiatry, psychoanalysis, mental deficiency, delinquency and maladjustments. It entails a long and intensive study in neuroanatomy, neuropathology, medical psychology, and clinical experience and training in the various subdivisions of neuropsychiatry.

2. A distinction is made between specialization in neuropsychiatry on the one hand

and superspecialization on the other.

3. Specialization in neuropsychiatry entails a broad and exhaustive study of the fundamentals of neuroanatomy, neuropathology, neurology, psychiatry, the psychoneuroses and allied forms of abnormal behavior. It carries with it a sense of satisfaction in being able to recognize the various subdivisions of neuropsychiatry and in being able to manage the total behavior of the patient. The neuropsychiatrist may, with benefit to himself and the patient, eventually limit his work to one subdivision of neuropsychiatry without impairing his general efficiency.

4. Superspecialization in neuropsychiatry is the limitation of one's effort to a subdivision in neuropsychiatry without any previous adequate training and experience in the other subdivisions. It enables a man to acquire proficiency in a very limited field, and to devote himself to intensive study and research in that field. It tends to create reputations, and indirectly to enhance the prestige of medical schools. The superspecialist is handicapped by his own inadequate training in other subdivisions of neuropsychiatry, and by the very limitations which such intensive superspecialisations.

cialization imposes.

THE THERAPEUTIC USE OF ANTIPOLIOMYELITIS SERUM IN PREPARALYTIC CASES OF POLIOMYELITIS*

By WILLIAM H PARK, MD, NEW YORK, N Y.

I is now definitely decided that poliomyelitis is due to a true filterable virus. This is of extreme importance since we know of no other disease due to a filterable virus that ean be benefited by an anti-scrum after clinical symptoms have developed. As we read of the attempts made to cure the discase we note that at first the scrim was advocated to be used, not only in paralyzed cases but in those in which the paralysis had existed for some days. Thus in France. Netter in 1915 treated intraspinally thirty-two cases after paralysis had developed and was en-Light of the thirtythusiastic about the results They were of the bulbar type two cases died In America, Zingher in 1916 treated, at the Willard Parker Hospital, eighty-eight cases Thirtyeight of these cases died At the Minturn Hospital he treated eighteen cases that were already paralyzed Fifteen recovered Zingher was less enthusiastic than Netter, but believed "the serum showed possibly, in a certain proportion of cases, an inhibitory effect on the further progress of the disease, which resulted in a saving of life." He added, "It is difficult to forecast, however, what the natural result of the disease would have been in these cases "

Neal, also in the research laboratory, who saw many cases both treated and untreated, noted no beneficial effects from the serium in the paralyzed cases. Since then, very few have seriously recominended the giving of the serium in cases al ready showing paralysis, but it has been given to a small percentage of cases where the person or

their families requested it Before the great epidemic of 1916, few recognized that there was a preparalytic stage in the disease, which could at times at least be diag-It was believed that the majority of these cases went on to develop paralysis. In the 1916 epidemic, Zingher treated fifty-four preparalytic eases with one or two intraspinal injections of scrim Forty-four of these (81 4%) recovered without paralysis, while five developed marked, and five slight paralysis His comment on the outcome of these cases treated with serum was "It is known that in poliomyelitis we have a group of abortive nonparalytic eases in patients who go through the premonitory symptoms, but do not It is difficult to state theredevelop paralysis fore, how many of the patients treated with serum would have remained free from paralysis without serum treatment It seems to me however that the action of serum in polioinyelitis is bene fieral and that human serum is indicated in the treatment of the acute stages especially in the preparalytic period of the disease" Neal, watch-

*Rend at the Ann al Meeting of the Medical Society of the State of New York at Buffulo N Y May 24 1932

ing treated and intreated preparalytic cases seen in consultation during this same epidemic, formed the opinion that the treated cases did no better than those not treated. She also feared that the increased fever and the marked cellular response of the cerebrospinal meninges in the presence of the serum might be harmful, at least in some cases.

In 1928 Aycock and Luther reported 106 cases of poliomy elius treated in the preparalytic stage. They used, for the administration of the serum, the combined intraspinal and intravenous routes. The mortality was only 0.92%, while in cases first seen in the stage of paralysis and who received no serum, it was 14 per cent. No paralysis developed in 36 per cent of the treated cases. They believed these results were favorable.

McEachen and his co workers reported the results of treating 107 cases occurring in 1929 in Manitoba. They gave the serum intramuscularly The dose was also small, being often but 25 cc Almost 94 per cent developed no paralysis. They concluded that the serum was of value in the preparalytic stage.

In the Lancet of February 27, 1932, there is a report by MacNamara and Morgan of the use of serium in an outbreak of poliomyelitis in Australia One hundred and thirty-three cases were treated in the preparalytic stage. Their decision was that the serium gave excellent results. Here, as in all the other cases, there were no controls to compare with the treated cases. The physicians feeling that they had no right to exclude any preparalytic cases from receiving the serium

In 1931, we have the report of Shaw, Thelander and Limpos of the use of serum in the cases occurring in California both in the preparabite and paralytic stage. In the fifty-three cases treated before the onset of paralysis 84 4% developed no permanent paralysis while on the thirty-nine treated after the development of paralysis, only 23 per cent remained.

Show in his article on early treatment in the booklet on "Practical Suggestions Regarding Poliomyelitis," supplied for the scientific exhibit prepared for the American Medical Association, states on page 24 reasons for caution in accepting the evidence obtained from treating cases without controls. They are in my opinion so weight; that I feel justified in quoting them

'In table 3 are presented the results of convalescent serum therapy given by a number of observers. From this it can be seen that the view that the method is of probable value resulted from each set of observations. Such an opinion should be viewed with respect, but results are fur from conclusive statistically, especially because of the almost insuperable difficulty in prop-

erly controlling clinical trials of this nature. It is, of course, possible for one's opinion to be influenced by the apparent effect on occasional cases treated with certain highly specific serums, without numerical results being conclusive. The most glaring error into which one is tempted to fall is the comparison of end-results in a series of treated cases with an untreated group selected at large, which latter group may fail to account for many mild or abortive unreported cases. In other words, cases which are diagnosed on the basis of early symptomatology and treated with serum must not be compared, as regards end-results, with those in which paralysis was the diagnostic criterion.

"The clinician must maintain a strictly critical attitude toward the study of results and be prepared later to abandon such treatment in the not altogether unlikely event that its utility be finally conclusively disproved. The clinical point of view must remain one of thoughtful inquiry rather than eager acceptance or impatient rejec-

tion of the method."

Before taking up the results obtained by the health department inspectors and the pediatricians serving the Academy of Medicine, I shall consider the very important communication of *Kramer, Aycock, Solomon and Thenebe.

The authors note that their earlier studies were not adequately controlled, and that a study of alternate series is essential to establish the value of convalescent serum. Such a study is not feasible under the conditions in Massachusetts; it should be made where opinion is divided as to the value of serum or where the supply of serum is insufficient for all the cases diagnosed in the early stage.

The epidemic in 1931 in Brooklyn and in Connecticut offered suitable conditions. studied in a hospital in Brooklyn and one in Hartford, patients treated in the preparalytic stage, and a similar untreated group. Of eightytwo cases studied in the preparalytic stage, approximately half had received human, convalescent serum by the intravenous and intraspinal routes. No patient was accepted for study if his illness had lasted more than 3 days on admission to the hospital; careful physical examination was made, including the testing of all muscle groups to eliminate cases with weakness. All cases reported had the physical and spinal fluid findings or preparalytic poliomyelitis. The patients treated were given convalescent serum immediately upon admission to the hospital. The dosage was 60 c.c. given intravenously at the first sitting, and 40 c.c. intraspinally in two sittings, 8-12 hours apart.

A second muscle examination was made usually within 24 to 48 hours after admission and again before discharge, usually two or three

weeks later. At the end of the study a complete muscle examination was done on all of the patients.

Of the eighty-two cases studied in Brooklyn and Hartford, forty-two, or 51% developed some paralysis, the number being about evenly divided between the two cities. Two deaths from respiratory paralysis were both in the treated group, one in each city. In the remaining cases, the average paralysis for the treated group in Brooklyn and Hartford combined was 12.1 and for the untreated group, 5.9. The average paralysis per case in the treated group in Brooklyn is 1.4, in the untreated 4.3; while in Hartford the average paralysis in treated cases was 20.4, whereas the untreated cases showed an average of 4.3.

The proportion of cases developing paralysis in Hartford and Brooklyn was about the same, but the outcome was different. This difference is due to the including of a relatively small number of severely paralyzed cases in the Hartford In Brooklyn when the outcome of the treated cases is compared with that of the parallel untreated cases, the weight of evidence is with the treated group. In Hartford, because of the five badly paralyzed cases, the results are reversed and the untreated group is favored. The outcome of cases with respect to the day of illness on which the patient received treatment seemed to give some indication that the irregular results in Hartford might be accounted for by the lateness of the treatment in several of the patients which developed severe paralysis, but no statistical deduction could be made. These cases had been included on the same basis as othersand the irregularity can be ascribed only to chance variation in a limited number of cases in a relatively mild outbreak.

They conclude: "This therapeutic test of serum more nearly approaches a controlled experiment than any previously made by the authors; no statistical evidence was obtained that convalescent serum is effective, but the reverse conclusion—that it is of no value—may not be drawn. The outcome of this study of controlled cases justifies its continuation on a larger scale."

Serum Treatment in Preparalytic Cases of Poliomyelitis in New York City During the 1931 Outbreak.

During the time that Kramer and Aycock were carying on their adequately controlled and carefully supervised tests, the polionyelitis committee of the New York Academy of Medicine in cooperation with the Department of Health were interested in the comparative results in a much larger series of cases treated in the homes and in the contagious hospitals of New York City. As the opinion as to the efficacy of serum in the treatment of preparalytic cases was about equally divided between those who favored it and those who did not, we had no difficulty in obtaining

^{*}Convalescent Serum Therapy in Preparalytic Poliomyelitis. New England J. Med., 206: 432-435 (March 3d), 1932.

about equal numbers of treated and untreated cases.

In order to test the comparative value of the different methods of giving the serum, we administered it to some of the patients by what we might call Aycock's method of combined intraspinal and intravenous injections, and by the Canadian method of subcutaneous injection. We also treated a considerable number of patients by the intravenous method alone or combined it with the intransuscular injection

The total dosage also varied from a minimum of 25 cc. to a maximum of 100 cc. We have carefully taken records as to the day of the disease at which the case was seen, its apparent severity, when serum was given and the time of the first

injection.

The presence of paralysis and, if present, its amount was noted at the end of three weeks and again after a period of from five to six months. The amount of paralysis was noted and recorded at this time, but this was not done in as much detail as recommended by Aycock. Full reports will be made at a later time by the Academy of Medicine and by the Department of Hospitals.

In the consideration of the days of treatment and the outcome, as shown in Table fig. 1, those persons treated in the first day of their meningeal symptoms showed somewhat better results than those treated later in this illness; still, even those in whom treatment was delayed showed remark-

ably good results. The results in the untreated patients were, however, equally good.

As shown in Table 2, the method of giving the serum made no appreciable difference in the outcome. Those who received it intramuscularly developed in a larger percentage some weakness, yet it was of a very mild form.

The results in patients treated with convalescent scrum by the pediatricians working under Poliomyelitis Committee of the Academy of Medicine are almost identical with the results in those receiving only the usual treatment (Table 3).

A careful study of the results given in the tables especially discloses the fact that there certainly is little or no statistical evidence of any difference between the serum treated and untreated patients with preparalytic poliomyelitis as observed by the pediatricians serving under the Poliomyelitis Committee of the Academy of Medicine and by those observing the cases in the hospitals for communicable diseases in the City. The slight difference in favor of the untreated patients may probably be attributed to the accidental inclusion of a somewhat larger number of graver infections in the treated patients.

The fact of the increased meningeal irritation caused by the intraspinal injection of serum might conceivably have some effect but this is not statistically proved.

The figures given in Table 4 are disappointing to those who hoped that the serum would demon-

strate its value statistically.

Some of us were hardly surprised for we knew that antiserums have been of little or no value in other diseases known to be due to filtrable viruses. These invade the cells themselves and seem then to be beyond the curative reach of the serum.

Not one of the pediatricians who treated these patients felt that he had seen any evidence of a curative influence of the serum.

Dr. Alfred Fisher and Dr. Milton Levine as-

sisted in collecting these statistics.

Conclusions

In summing up, we can say that statistically there certainly was no evidence that the serum did any good; also, as stated by Kramer and Aycock, there is no evidence that it did any serious harm. The results of these two controlled investigations, certainly indicate that we should, wherever possible, treat only a portion of the cases with serum, and observe equally carefully the cases not treated. In this way we may finally come to a conclusion whether the serum is of any value, at a time when the spinal cord is already invaded by the virus of poliomyelitis.

Personally I think the treatment with convalescent serum cannot be given early enough to be that the serum may be of value as a preventive just as in the case of children recently infected

by the measles virus.

SERUM TREATMENT OF MENINGITIS*

By JOSEPHINE B. NEAL, M.D., NEW YORK, N. Y.

THE treatment of meningococcic meningitis by a potent serum properly administered is highly gratifying. Unfortunately, there is no laboratory test which adequately measures the therapeutic power of the serum and the best treatment of any individual case is largely a mat-

ter of experience.

Meningococcic meningitis shows wide variations in its severity in different outbreaks. Since 1910, when the service for meningitis was established by Dr. Park, there has been no real epidemic in New York City. In 1917 and 1918 and again in 1928, there was a sharp increase in the number of cases but at neither time was there a large number of the severe fulminating types that have been described in epidemics in other localities. It is probable, therefore, that we have pursued a more conservative method of treatment than we would have found necessary had an epidemic of the most virulent type arisen. During the past 22 years, our division has had under its care or has advised in the treatment of more than 1,100 cases of meningococcic meningitis. have emphasized repeatedly that it is impossible to formulate a method of treatment which is applicable to all patients and to all types of the disease. We believe that in general, a conservative method of treatment is the best. We have studied the results in hospitals where more intensive methods of treatment have been employed and the comparison of their results with ours has seemed to justify this conclusion.

Our method of treatment is usually as follows: Whenever a lumbar puncture yields a cloudy or hazy fluid, antimeningococcic serum warmed to

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

body temperature is immediately administered intraspinally by gravity. Further serum treatment will depend on the cultural examination of the fluid, but all cases of purulent meningitis are treated as being of the meningococcic type until they are proved to be caused by some other organism. The intraspinal administrations of serum are continued about every twenty-four hours until at least two successive specimens of the fluid show no organisms by smear or culture. dose of serum is usually twenty c.c. if as much or more, fluid has been obtained. If the amount of fluid withdrawn is great and the serum runs in easily by gravity, without untoward symptoms on the part of the patient, thirty to forty c.c. of serum may sometimes be administered. On the other hand, in certain instances when only a small quantity of fluid is obtained, we may inject more than the amount of fluid withdrawn provided the serum runs in easily and no unfavorable symptoms result. It is desirable to drain the subarachuoid space as completely as possible before injecting serum, but if the fluid is under greatly increased pressure, care should be taken to withdraw the fluid slowly. Using this precaution fifty to sixty e.c. or more of fluid may be safely withdrawn. If headache develops during the removal of the fluid it usually quickly disappears when the serum is injected. Almost the only condition under which we inject serum oftener than once in twenty-four hours is when the fluid is under so greatly increased pressure that a puncture at more frequent intervals seems indicated to relieve it. This condition rarely occurs.

Some physicians have recommended graduated doses of serum for young children depending

rither arbitrarily on the age. We have not found this necessary. We depend rather on the amount of fluid withdrawn and the ease by which the serimi runs in by gravity in determining the size of the dose. But it is necessary to exercise more than ordinary erre in removing fluid and injecting serium in joing habies.

It is rarely safe to give fewer than four doses of serum. A case of average severity will require perhaps from six to ciglit doses, and cases are occasionally seen where twenty or more doses of serum are necessary before the fluid becomes sterile. As his been stated the serum treatment is continued until two successive fluids are free from organisms This is by far the most important indication for stopping treatment indication of less value, is the return to normal of the spinal fluid sugar The cell count of the spinal fluid is, by itself, of comparatively little value, since the cell counts of different nortions of the spinal fluid will show variations, and since the prognosis is pour when the spinal fluid be comes elearer and the organisms persist. When two sterile spinal fluids have been obtained it is usually safe to stop the scrum treatment temporarily at least. It is often necessary to do several lumbar punctures during eonvalescence for the relief of pressure, and these fluids should be carefully examined and cultured as the return of organisms would indicate additional serim treat-We have emphasized the laboratory tests as a guide to the administration of the serum as it is rare indeed that the chinical picture is not accurately reflected or even predicted by the changes in the spiral fluid. If, however, the symptoms do not improve after the fluid becomes sterile, and the serum has been temporarily discontinued it is well to resume the injection of the serum as the symptoms may be due to a localized meningitis with adhesions which may be favorably influenced by the continued use of the serum

If signs of blocking develop recourse should be made to ventricular or disternal punctures and the administration of serum by these routes. In babies where the fontanelle is still open ventricular puncture is to be preferred to disternal as it is less dangerous to the patient and more certain of success, since the block is quite as likely to be above the cistern as below it have occasionally encountered cases where little or no fluid has been obtained by lumbar puncture and yet serum has run in easily by gravity, and there have not been signs of increased pressure Several such cases have made satisfactory recoveries without resorting to ventricular or cisternal punctures We are, perhaps, more conservative than many in doing ventricular or disternal punc Comparatively few babies where repeated ventricular punctures have been necessary have recovered We do not believe that we know at present what may be the after effects of the repeated training to the brain tissue. As regards

eisternal puncture, we do know that death has occasionally followed promptly, due usually to hemorrhage. It seems unfortunate that these fatalities are not reported, as we not infrequently read accounts of large series of cases without accident written by physicians using this technic in patients with syphilis of the central nervoirs system. The dangers are much greater when there is an active inflammatory process with layers of adhesimis in the neighborhood of the cistern as is likely to be the case in meningitis.

Cisternal punctures should be attempted only those who have had adequate practice on the cadaver

It is important, after doing two or three ven tricular or eisternal taps, to again attempt lum bar punctures. In this way we can determine whether or not the block has been relieved. The relief of the block obviously prevents the devel opinient of obstructive hydrocephalus, but in certain instances a communicating hydrocephalus arms result.

In regard to the intravenous or intramuseular injection of seriim, we believe that this is indicated only in cases of meningococeie senticenin without meningitis or in those cases of menin Litis which show a prolonged invasion of the blood stream by the organisms as indicated by repeated positive blood cultures or a rash that shows a tendency to persist or to recur. While it is probable that in practically all eases of men ingitis there is an invasion of the blood stream early in the disease we think that in the very great majority of cases this invasion is transitory and that injections of serum other than intrasor nally are unnecessary. In some instances this has been proved by blood culture and in many more it has been very definitely established by the rapid fading of the rash and the clinical improve ment of the patient. In a series of 43 patients 21 of whom had a hemorrhagic rash at the time the blood culture was taken there was a positive culture in only three instances. The intravenous administration of the serum is not without dan ger as a severe or fatal reaction occasionally fol lows Several such instances have been brought to our attention. Certainly patients tolerate serum much more easily by the intraspinal than by the intravenous route

We are frequently called to see patients who are not responding satisfactorily to treatment. This may be due to the fact that the serum being used is of low potency. A change of serum is therefore advisable. Unfortunately, there is no reliable laboratory test for the therapeutic properties of serum. It is possible that the meningitis may be due to an aberrant strain of the organism which is not represented in the serum. This point is somewhat theoretical as the grouping of the strains of the meningococcilis is by no means sharply defined.

In some of the obstinate cases we have substi

tuted an antibody preparation after the ordinary serum had failed to produce results. In a general way it may be stated that, when a satisfactory preparation of antibody was used, the results were generally especially favorable. The agglutinating titer of the antibody preparations has been much higher than of the serum from which it was made. We hesitate, however, to stress the value of the agglutination test, as we have observed that it does not run parallel with the therapeutic action of the serum. While we realize that the antibody preparation is still in the experimental stage, our experience with it leads us to believe that it may be so developed as to be much more effective in the treatment of epidemic meningitis than the serum as ordinarily prepared.

We are thoroughly convinced that in a certain number of cases unsatisfactory progress is due to overtreatment. While the exact way in which the serum exerts the curative action is not entirely understood, it would seem that its chief action lies not in a bactericidal power, but in increasing the phagocytic action of the cells or in so affecting the organisms that they may be more easily ingested by the cells. Tapping of the spine at very frequent intervals, it seems to us, would remove many cells that had been stimulated to a high degree of phagocytosis. Furthermore, as serum injected intraspinally does not entirely pass out of the subarachnoid space for about twenty-four hours, its more frequent administration seems to us illogical. Aside from the theoretical considerations, performing a lumbar puncture and administering serum two to four times daily subjects a patient to considerable pain and discomfort, and keeps him in an almost constant state of local reaction to the serum. By this reaction we mean the rise in temperature and increased meningeal symptoms and restlessness which in the great majority of instances takes place in two to four hours after the serum is injected and continues for a varying length of time. Then too, horse serum is a foreign protein that must be eliminated and that usually shows definite evidence of being more or less toxic. We are not at all convinced that the large quantities of serum that are given when the patient is intensively treated, may not be actually harmful in a certain percentage of instances. At any rate, we have frequently been called to see patients who have been treated rather intensively but have failed to make progress. In many of these cases progressive improvement followed the elimination of further use of serum.

In many cases that have become chronic and in a few patients that have reacted unfavorably to serum, we have used an autogenous vaccine sub-cutaneously or intraspinally. We have on record a number of patients who have responded favorably to vaccine therapy, after becoming refractory to serum.

Mortality

During recent years a larger proportion of cases of meningitis have been sent to hospitals. In many institutions we are called to see only the patients who are failing to respond to treatment.

In analyzing our cases of meningococcic meningitis for the past five years, there are 302 for whose treatment we were responsible. Most of these were treated in their homes in cooperation with their family physicians. The remainder were in hospitals under our direct supervision. Of these 302 cases 57 died—a mortality of 18.3 per cent.

Of the 57 fatal cases, 7 received only one in-

iection of serum.

The results of the serum treatment of other forms of meningitis are disheartening. Nevertheless, every effort should be made to give the individual patient the benefit of any form of treatment that may be of value. Occasionally, patients suffering from various forms of meningitis recover, but we can seldom honestly attribute the recovery to any particular method of treat ment.

As to our own experience, none of our patients with pneumococcic meningitis have recovered, although we have used the appropriate type of serum either alone or in combination with numoquin hydrochloride. In spite of the disappointing results, we still continue using the serum. Six recoveries have taken place of 164 cases of streptococcic meningitis In two of these, the action of the serum (antiscarlatinal) seemed really specific. They followed scarlet fever, and in spite of a long and stormy course recovery occurred. In the other cases, we were more doubtful as to the value of the serum.

Influenzal meningitis scens to offer more hope for successful treatment than other forms not due to the meningococcus, since it usually runs a more sub-acute course. Of 90 cases of influenzal meningitis under our care, 3 have recovered. But in most of them, we could not definitely ascribe the recovery to the influenzal serum. We are more impressed with the marked though temporary improvement in clinical symptoms and in the spinal fluid that has so often followed the use of the serum. It is, therefore, my impression that a more potent serum may be developed which may yield better results.

In spite of the discouraging results so far obtained, it is imperative to continue our efforts to find a more satisfactory method of treating these so highly fatal forms of meningitis. It is well to remember at times a quotation from Thoreau: "Nothing is denied to well-directed, persistent

effort."

HE USE OF CONVALESCENT SERUM IN THE TREATMENT OF MEASLES, HICKEN-POX, MUMPS AND WHOOPING COUGH, INCLUDING THE PROPHY-LACTIC VALUE OF PARENTAL BLOOD*

By I M LEWIS MD, AND L H BARENBERG, MD, NEW YORK, N Y

THE high morbidity and mortality associated with measles in infants and young children, particularly those housed in institutions rges the use of a procedure that will either preent or modify this disease. To accomplish this nd, Nicolic and Conscil in 19181 recommended he serum of patients convalescing from incasles t is now well established that convalescent nersles serum is very effective in preventing nersles when given in sufficient doses in the ourse of the first five days of the incubation peiod and in attenuating the disease when given somewhat later in the incubation period or in In spite of its great clinical maller amounts value, however, convalescent serum has not come into general use, chiefly because of the difficulty encountered in procuring it Cases of mersles in adults are uncommon, and in the case of children parents are reluctant to allow blood to be withdrawn, especially during convalescence

The permanent immunity that almost in variably follows one attack of measles and the fact that a mother who has hid incasles imparts to her offspring sufficient anti-bodies to render the infint immune for the first few months of life indicates that most adults have an approciable amount of these immune bodies in their blood It was, therefore, logical that the value of adult blood in the prophylaxis of measles should have been investigated. In 1920, Degk witz inoculated adult serum into seven children who had been exposed to measles, six receiving 30 cc and one 20 cc of scrum. Four of the seven developed measles but in an attenuated form One veir liter Reitschels reported good results from use of adult blood. Later. Salomon,4 Gerlich, Hilsinger, Kovacs and others abroad and Zingher 8 Karelitz and Levin, Bivings, 10 Bader's and Van Cleve' in this country reported favorable results with the use of adult whole blood or serum as a prophylactic measure against measles

An epidemic of measles broke out in the Home for Hebrew Infants in the Spring of 1929 and lasted two months. This Institution harbors ap proximately 325 children, about 150 being under 2 years and the remainder from 2 to 4 years of age. The death rate in the institution has been highest during those years in which measles his occurred, the increase in mortality having resulted from complicating pneumonal or empyema. At the beginning of the epidemic considerent measles serum was not available but since the reports of the use of adult whole blood

were so encouraging it was decided to employ this agent as a menus of modifying the chiracter of the epidemic. Accordingly, 56 children from 2 to 4 years of age were given intramuscular mijections 30 cc of whole blood which was obtained usually from the parent of the child after careful history had been obtained to eliminate the possibility of tuberculosis or syphilis. It may be added that the injections were well tolerated and that in no instance was a rise in temperat renoted.

As the epidemic progressed we were able to obtain convalescent serum from some of the children and also from three of the nurses who developed the disease. This form of treatment was given to 64 children. Twenty three children did not receive injections of any kind and served as controls.

Results

The entire immoculated group of 23 children came down with measles which in no instance eould be classed as modified or attenuated, and therefore an excellent opportunity was afforded of evaluating the prophylaetic merits of parental Thirteen or 23 per cent of the 56 children receiving 30 cc of blood remained free from the disease, although they had been exposed to measles throughout the epidemic Of the 43 children who developed measles, 23 were of the modified or attenuated type thus 36 children or 64 per cent of this group were definitely bene fited by the use of adult whole blood Of the 20 children who were not protected, seven received the injection of blood somewhere between the seventh and tenth day of the incubation period, which was obviously too late, and ten received blood from 12 to 23 days before they actually contracted measles, at which time they were no longer protected by the blood previously injected It should therefore be emphasized that in order that the measles be modified by the use of this procedure, blood must be inoculated during the first five days of the incubation period, or from one to eight days prior to infection

In institutions and in hospitals where there are usually a number of successive outbreaks in order to insure attenuation of measles in almost every child who develops the disease, it would be necessity to repeat the injections of blood every 12 days in those who have not as yet come down with the disease. In private homes, however, since children are in closer contact, infection almost always follows exposure to measles and therefore a single administration of 30 cc of blood will almost always bring about an atten-

^{*}Real at the At that Meeting of the Melical Society of the State of New York at Buffalo N Y May 24 193?

uated form of measles. The attenuated type of measles in our series was characterized by a slight to moderate increase in temperature with an average duration of three days; the eatarrhal symptoms were either absent or very mild; Koplik spots were present in about 50 per cent of the cases; the rash in some instances was scanty, in others widespread but never confluent. Of great importance was the fact that these children did not appear ill. They were almost invariably either sitting or standing in their beds and showed no signs of discomfort. No complications developed.

Convalescent Serum

Sixty-four children received 6 cc. of eonvalescent measles serum which was obtained either ten days or thirty days after defervescence. Forty-four or 73 per cent remained completely protected. Of the 16 children who developed the disease, 14 came down with a markedly attenuated form of measles. One of the two children who developed measles of moderate severity received the serum on the last day of the in-No complications were obcubation period. served in this group. It may be added that the thirty-day serum seem to be just as potent as the ten-day serum. Convalescent serum was therefore of particular value in preventing the disease, whereas adult blood was effective in bringing about attenuated measles in a high proportion of the children. This form of disease is highly desirable for children of private homes, since permanent immunity also results from an attack of attenuated measles. In institutions and hospitals complete protection should be the goal. With the injection of 30 cc. of blood, complete prevention was brought about in only 23 per eent of the children. Had we used a larger amount. the percentage of complete protection undoubtedly would have been higher. Since it is difficult to inject intramuscularly more than 30 cc. of whole blood, it is necessary to use blood serum if a larger amount of anti-bodies is desired. amount of adult blood serum which will bring about absolute protection against measles is not definitely known, but we should estimate that about 40 cc. of serum would be sufficient to protect completely infants and young children up to four years of age and somewhat larger quantities for older children.

Chicken-Pox

Chicken-pox is one of the mildest of the contagious diseases of childhood, and it is therefore obvious that one would-not desire to bring about an attenuated form of this disease. However, it is not an uncommon experience for institutions and hospitals to have their wards quarantined for weeks or even months on account of succes-

sive outbreaks of chicken-pox. It is therefore of great importance to make use of a procedure which will eheck further cases of varicella in such institutions. It has been shown by Blackfan. Petersen and Couroy,13 Mitehell and Ravenel.14 Weech15 and others that 5 to 6 cc. of convalescent serum will prevent this disease in about 90 per cent of the cases if given during the first few days of the incubation period, but as has been pointed out with measles, it is rather difficult to obtain convalescent serum when it is needed. We therefore attempted to determine the amount of blood from adults who have had the disease during childhood, which would be necessary to prevent chicken-pox. Five infants received 30 cc. of whole blood and 8 infants received 40 cc. of serum from a professional donor. All of the infants who received 30 ce. of blood developed chicken-pox in a mild form but not one of the eight infants which received 40 cc. of serum eame down with this disease, so that this amount can be relied upon to prevent the development of chicken-pox in infants. Larger amounts may be required to prevent the occurrence of chickenpox in older ehildren.

Mumps

Hess¹⁶ was the first to use convalescent serum in the prevention of mumps. In 1915, he injected 3 to 4 cc. of serum intramuscularly into 12 susceptible children and not one child developed the disease. In 1925, Regan injected 2 to 4 cc. of serum into 70 children and only one child developed mumps. In 1931 Barenberg and Ostroff¹⁷ reported results of the use of convalescent serum in an epidemic that broke out in our Institution. Twelve cc. of blood (5 cc. serum) obtained from patients convalescing from mumps were given to 40 children who were exposed to this disease, 125 children served as controls.

Six out of 40 treated children developed mumps, an incidence of 15 per cent, whereas, 49 out of 125 untreated children developed the disease, and incidence of 39 per cent. The course of mumps was much milder in the treated series. The epidemic lasted only two months which was a much shorter time than the duration of previous epidemics at the institution, and would have been undoubtedly curtailed still further had larger quantities of serum been used. basis of this experience, we would recommend 12 to 15 cc. of convalescent serum if one is desirous of obtaining complete protection which should be the aim in hospitals and in institutions. We have had little experience with the use of adult blood in the prevention of mumps. Last year, 11 children received 12 cc. of blood from an adult who had had mumps in childhood, but this quantity was not sufficient to bring about a modified attack of mumps. Deducing from our experience in measles, 30 cc. of blood obtained from an

adult who has had mumps probably would bring about a modified form of numbs.

Whooping Cough

It might be of interest to mention our experience during the past winter in regard to the prophylactic effect of normal adult blood on the course of whooning cough. Seventeen children in one of our wards were exposed to this disease; six received 30 cc. of blood and 11 served as controls. This was a very good opportunity of testing the value of adult blood in whooping cough, as the children were harbared in the same ward and thus the diet, hygiene and nursing care were similar for both groups, and of still greater importance was the fact that the children had been exposed to the same source of whooping cough, in other words, to organisms of the same strain or virulence. The results of this experiment may be summed up in a few words; All of the six children that received blood developed whooping cough which however was of lesser severity than that of the controlled group. Of the six treated children, the course of whooping cough was mild in five instances

and moderate in one, whereas of the ten untreated, two were mild, three were moderate and five It was necessary to administer codine to three of the severe cases in an attempt to reduce the number of paroxyms. The results following the inoculations of adult blood were definitely superior to those obtained with the use of pertussis vaccine.

Recapitulation

Convalescent serum is very effective in preventing the development of measles, chicken-pox and mumps but its application is limited because of lack of availability.

If one is desirous of preventing measles. chicken-pox or mumps and convalescent serum cannot be obtained, the serum of adults who have had these diseases should be employed and complete protection may be expected in a large percentage of cases.

For attenuation of measles after infection, the blood of adults who had previously had measlesis of great value.

Adult blood is also of value in modifying the course of whooping cough.

DISCUSSION FOLLOWING "SYMPOSIUM ON THE THERAPEUTIC USE OF BIOLOGIC PRODUCTS," NEW YORK STATE MEDICAL SOCIETY, BUFFALO, MAY 24, 1932

By AUGUSTUS WADSWORTH, M.D., ALBANY, N. Y.

Director, Division of Laboratories and Research, New York State Department of Health, Albany.

HTHERE were a few points in the papers just presented on which our experience at the state laboratories may be of interest. I wish particularly to stress the recommendations of Doctor Neal regarding the continued intensive treatment of meningococcus meningitis by the intraspinous method. I think it is unfortunate that there has been a tendency on the part of some physicians to substitute intravenous injection for intraspinous. The bacteremic form of the disease does occur and intravenous treatment may be of importance in those eases but, with meningeal involvement, it should supplement, not supplant, intraspinous treatment. As I have reviewed our reports on the use of different sera in the treatment of meningitis over a number of years, I have been impressed with the close correlation between the laboratory standardization by the agglutination test and the clinical results. I think the reflection on standardization by the agglutination test has come largely from the practice of testing cultures freshly isolated from the cases, with the serum to be used in their treatment. Many eultures do not agglutinate when recently isolated and thus this practice is no griterion of the effectiveness of the serum. A very important factor, however, in the production of the serum is the selection of strains for the immunization of horses.

I think it is of great value to follow the serum treatment of scarlet fever and erysipelas, especially with due regard to the potency and valency of the serum used. From the beginning, we have questioned the establishment of a specific streptococcus as the etiologic agent of any form of streptococcus infection and the results of our investigations have supported that position fully. The serum which we have prepared and distributed is monovalent and not concentrated. The sera which have been generally available, although polyvalent, have, according to our very thorough study, lacked potency and valency—and to such an extent that a year ago the Public Health Council of the state established, independently,

minimum standards of potency for, and methods of testing, sera that are offered for sale in New York State, exclusive of New York City. The reports of the treatment of scarlet fever have, I think, been colored by the fact that sera of high potency and broad valency have not been available and that the dosage has not been adequate for the treatment of severe infections.

The reports on the use of the scrum which we have distributed now include many forms of streptoeoccus infection-over 1,000 eases of scarlet fever, approximately 200 of erysipclas, and a miscellaneous group including septic sore throat, cellulitis, mastoiditis, and puerperal infectionsome of them with bacteremia. The results in the treatment of scarlet fever confirm the conclusions of previous observers; namely, that the serum is most effective in eases predominantly toxemie, whether mild or severe. The general impression that the serum has no effect on the complications may be questioned, especially since the potency of the sera generally available has been so unsatisfactory and the doses have been so utterly inadequate for the treatment of streptocoecus infection eharacterized by a bacteremia or a parasitie invasion of the tissues. Doses of from 10,000 to 20,000 units should be used in such cases and should be repeated at twelve- or twenty-four-hour intervals if necessary.

The full report of these studies was presented at the May meeting of the Association of American Physicians at Atlantic City and will appear in the Transactions; also before the Section on the Practice of Medicine of the American Medical Association and has been published in the Journal.

The scrum therapy of streptococcus infection should be developed from a broad point of view in order to have scrum of high potency and broad valency available and especially since there is no other treatment that is of avail, and despite the fact that, until the valency covers all strains, certain cases of scarlet fever, erysipelas, or any type of infection may fail to respond to the serum.

Annual Meeting, April 3-5, in the Waldorf-Astoria, New York City.

SCIENTIFIC EXHIBIT

A scientific exhibit is planned for the Annual Meeting of the Medical Society of the State of New York, to be held April 3-5, 1933, in the Waldorf Astoria, New York City. The exhibit will be located within easy access of the other features of the Annual Meeting, and will be of practical value to general practitioners of medicine. Invitations to take part

in the exhibit are extended to physicians, nedical schools, and laboratories; and applications for space and information should be made to Dr. Frederic E. Sondern. 20 West 55th Street, New York, Chairman of the Committee. The number of applications which have already been received, assures the success of the exhibit.

TESTS FOR DRUNKENNESS

It is a surprising fact that very little original work or research has been done on the subject of alcoholic intoxication, especially in the development of tests that are simple and reliable. The discussion now taking place in The Congress regarding the intoxicating qualities of beer reveals a multiplicity of opinions, but few accepted facts, as is shown by quotations from prominent authorities printed on page 44 of the January first issue of this Journal.

Everybody knows that "alcohol makes a person drunk," but that assertion involves two unknown

quantities:—

(1) How much alcohol is needed to produce

measurable effects of intoxication.

(2) What constitutes drunkenness or intoxica-

If ten per cent of the huge sums of money spent in propaganda, both for and against prohibition, were devoted to scientific investigation of the effects of alcohol on the human body, the question of stimulation and intoxication would be lifted from party belief and controversy into the realm of scientific demonstration.

Let anyone engage a group of physicians in discussion of the effects of a glass of whiskey on the human body and mind, and he will get replies as diverse as those which laymen would give.

Search the medical literature and one will find only meagre records of accurate observations on the milder stages of drunkenness. Any reliable investigation of alcohol is therefore a valuable contribution to the cause of true temperance.

An original record of value is contained in the December, 1932, issue of the Pennsylvania Medical Journal, in which Dr. Heise and Dr. Halkorn of Uniontown, Pa., describe tests which they applied to 200 persons charged with driving automobiles while drunk. Their basic test consisted in estimating the percentage of alcohol in the urine, and correlating the findings with psychological tests and the case histories. The judges and lawyers at first were openly skeptical about the tests, but they realized their reliability and value when the urines of persons with brain injuries were proved to be free from alcohol, and intoxication was thereby excluded as a cause of the symptoms. It was then but a step to the acceptance of positive urinary findings as indicating alcoholic intoxication.

The authors conclude their paper—"We wish to acknowledge our gratitude to the innumerable persons who have offered to drink whiskey for the sake of science, and also to the attorneys for the defense, whose 'razzing' has furnished the incentive for this paper."

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Animal Experimentation:—The "antivivisectionists" were with us a quarter of a century ago and as active along the same lines of legislation and propaganda as at present, as is shown by the following editorial in this Journal of January 1, 1908:

"The signatures of medical men in this State are being solicited to a petition in favor of a proposed bill entitled an 'Act to prevent cruelty by regu-

lating experiments on living animals.'

"The bill specifies in which cases anesthetics must be used, while the fact is that the habitual use of anesthetics in laboratories has long been practised.

"It is also most injudicious that a system of reports should be established by law, so that the system might readily become a means of persecution, should the State Commissioner of Health be perverse, or yield to the pressure of the agitators by whom the administration of the law would be jealously watched.

"The persistency of agitators regarding experiments on animals would make the proposed law merely that 'entering wedge' that 'first instalment' for which some of them have long clamored. The passage of the bill in question would not forestall further agitation, as is claimed; it would incite to it. This is abundantly clear from the foreign experience of thirty years.

"Let no medical man of the State of New York sign the petition to change the present laws, which amply suffice for the purposes of scientific experiment, and, should the case ever arise, for the pun-

ishment of wrong doing."

MEDICAL PROGRESS

Chronic Progressive Chorea -In reviewing the history of chronic progressive chorea, Stmon Stone quotes Huntington's original description of the disease, in which he writes 'There are three marked peculiarities in this (1) Its hereditary nature tendency to insanity and suicide (3) Its manifesting itself as a grave disease only in adult Davenport has traced the origin of the disease in the United States to the seventuenth century, when three chorese brothers migrated to Connecticut Their descendants spread over Connecticut Massachusetts, Rhode Island, and New York, and by 1909 about 4,300 descend ants of the original choreics were tabulated and studied by Davenport and Muncie They find that because of intermarriage with normal individuals, a number of biotypes have arisen showing some modifications of the eardinal symptoms described by Huntington they have classified as follows (1) A type in which tremors are present and no mental deterioration (2) Tremors absent and mental deterioration present (3) Non-progressive elio rea (4) Chorea beginning in early life instead of adult age (5) Mental symptoms preceding by years the onset of choreiforn movements Stone reports 5 cases, 2 with no family history of chorca and 3 in two chorese families with a total of 218 members, among whom 23 have suffered from the disease. He finds that the symptomatology varies not only in different families, but also in members of the same fam ily Huntington's impression of nervous instability among unaffected members of choreic families was verified by Davenport and is apparently borne out by his own studies. A history of alcoholism was frequently obtained among unaffected members also a history of nervousness and maladjustment. No valid explanation of the disease has been found. The diagnosis is rather simple in advanced cases exhibiting choreiform movements, characteristic gait, speech defect and mental changes, together with a family history of chorea. The prognosis is practically hopeless though the disease may last as long as twenty years before the patient dies. No drug is known that will completely arrest the progress of the disease Stone has obtained some temporary improve ment with arsenicals and luminal Stramonium in increasing doses, until 12 to 15 cc daily are administered has given the most no ticeable results. Under this treatment in one of the milder cases choreic movements entirely disappeared, and in three cases in which other

therapy had failed the stramonium treatment was followed by a marked reduction in the number and extent of the movements. Because of its strong hereditary tendency and the fact that it incapacitates an individual in the prime of life, Huntington's chorea has a certain social importance. Members of choreic families should refrain from having children—New England Journal of Medicine December 1, 1932 cevii, 22

Vascular Reactions to Heat and Cold -Sev eral months ago the idea came to Th. Brosse, J Lenegre, J Mage and A van Bogaert to undertake to characterize by objective findings, as for example by an abnormal reaction to a mode of excitation, the subjective and object tive disturbances experienced by certain patients and habitually attributed to an anomaly of the local circulation. They accordingly studied the reaction to heat (42° C) and cold (7° C) in 9 normal subjects with supple arter ies and in 24 individuals, either old or young, with sinuous or indurated arteries. As criteria of the vascular reaction they chose the variations in the amplitude of the arterial pulsations and in the diastolic pressure, the former revealing the reaction of the walls of the large and medium sized arteries, and the latter the condition of the terminal elements of the arterial For purposes of precision, in order to prevent variations of systolic pressure from in fluencing the amplitude of pulsation the comparison was made under conditions of counter pressure immediately above the minimal pres sure, and for further accuracy, a complete os cillometric curve was registered from centi meter to centimeter, or for every two centimeters, of mercury in every examination. Thus the amplitude of pulsation under all counterpressures from maximal to minimal, was registered in all subjects before the 20 minute bath, and every 5 minutes during the course of each bath It was found that in the young normal subjects heat increases the amplitude of arterial pulsations at all counter-pressures, but especially at those immediately above the minimal pressure, it generally lowers the minimal pressure, but sometimes fails to modify it The reactions occur most frequently at the fifth minute of the warm bath, and always by the tenth Cold on the other hand reduces the amplitude at all counter pressures and raises the minimal pressure. In the subjects with deteriorated arteries the results were in most cases the same; but in 5 cases the diastolic

pressure was raised instead of lowered by heat, and in 2 cases the amplitude of pulsation was considerably increased instead of diminished by cold, without the minimal tension changing. The authors regard as pathologic reactions to cold and heat: (1) a lasting and progressive increase of diastolic tension under heat, observed in several arteritics; (2) a lasting and progressive lowering of diastolic tension under cold; (3) an increase of amplitude of pulsation under cold, at all counter-pressures, but principally at just above minimal, when the minimal does not change; and (4) a diminution of amplitude under heat, principally just above the minimal tension, whatever may be the modifications of the latter. In these cases cold dilates and heat contracts the walls of the large arteries and their terminal arborizations .-Archives des Maladies du Cœur, October, 1932.

Heredosyphilitic Tabes.—The existence of heredosyphilitic tabes is today an incontestible fact, according to J. Chalier, H. Naussac and I. Boucomont. On the basis of a study of 128 cases found in the literature and 2 personal cases, they assert that heredosyphilitic tabes in children presents certain differences in its course from that in adults. While the meningeal lesions of tabes of hereditary syphilis in the adult are practically the same as those of acquired syphilis, this is not true in the juvenile form. Here the affection presents a forme fruste, with a poverty of symptoms and a slow evolution that render it what must be called an abnormal tabes. The first symptoms are not generally, as in the adult, pains or ataxia, but are more likely to be either troubles with vision (amblyopia) or with micturition (incontinence). The ocular or the vesical disturbance, as the case may be, remains for a long time the only symptom; it may increase, diminish, or remain stationary, while the other symptoms. such as absence of reflexes, Romberg's sign, ataxia, gastric crises, pains, etc., may not appear until a very late period. Thus a child may become blind, and several years elapse before the tendinous reflexes are lost. In a case of Marjoulis characterized by incontinence of urine it was 3 years before any other sign of tabes appeared. The slowness of the evolution of the affection makes its course doubly abnormal. This abnormality is the greater, the younger the subject. Hence the diagnosis in children presents great difficulty, since in the absence of numerous characteristic tabetic symptoms the physician does not think of this affection as a rule. In 16 cases of adult heredosyphilitic tabes, symptoms did not begin till after the age of 20. These accordingly represent 12.4 per cent of the 128 cases studied, and juvenile cases 87.6 per cent. In 10 of the 16

adult cases hereditary syphilis was easily established; in the other 6 it was only presumed, there being no indication whatever that syphilis had been acquired. In order of frequency the symptoms of tabes in these adult cases were fulgurating pains 11, ataxia 7, optic atrophy 7, bladder troubles 5, ocular paralysis 3, gastric crises 2, arthropathy 1. In reaching a diagnosis, differentiation must be made from syphilitic meningitis and Friedreich's disease, as well as from tabes of acquired syphilis. A word of warning is uttered against discarding the idea of syphilis altogether for lack of signs of acquired syphilis.—Journal de médecine de Lyon, November 5, 1932.

A Follow-Up Report on the Clinical Study of Cardiac Asthma.-In 1929, Palmer and White published an analysis of 250 cases of cardiac asthma. Because this is by far the largest collection of these cases in the literature, Sylvester McGinn and Paul D. White present this follow-up report. Of the 250 patients 230 have died. The records in these cases show that cardiac asthma occurs most frequently in males over fifty years of age with hypertensive or coronary heart disease. The average expectancy of life has been found to be a little more than two years, one patient out of four dving within six months. There were 72 patients who lived more than two years. It is evident that the better the treatment the longer the life. Rarely a patient may become free from attacks. The prognosis is much more serious vi cardiovascular syphilis is the underlying factor or when cardiac asthma is associated with congestive failure, aortic regurgitation or auricular fibrillation. The presence of pulsus alternans, gallop rhythm or very severe long attacks likewise makes the outlook dubious. The outstanding findings in 15 post-mortem examinations were chronic passive congestion and left ventricular hypertrophy. The most effective treatment of acute attacks of cardiac asthma consists in the hypodermic injection of morphine and the assumption of the upright position. Venesection is rarely required, but should be carried out in severe attacks. Hemostasis by the application of tourniquets to the extremities was not used in these cases. In another series of 22 cases all the patients were warned against overexertion, advised to rest in the most suitable surroundings, with the head elevated, and were given constant maintenance doses of digitalis after full digitalization. The maintenance of an adequate digitalis effect is of the greatest value in most cases for the prevention of cardiac asthma and the prolongation of life. A few patients find small daily doses of brandy helpful. Diuretics such as theocin and mersalyl (salyrgan) have been prescribed for the slightest evidence of decompensation and have been given at intervals when there has been no sign of congestive failure -New England Journal of Medicine, December 15, 1932, ccvn, 24

Adamantinoma of the Tibia: Etiology and Pathogenesis -B J Ryrie reports a case of ad mantmoma of the tibia and states that only two other cases of the kind have been recorded namely, that of Fischer (1913) and that of Baker and Hawksley (1931) In each case there was a history of trauma, slight so far as surface mjury was concerned, and the trauma was followed by a tumor after a latent period. In each case the tumor was one of the hone and periosteum and not of the soft parts. The Instology of the tumor was the same in all cases, being that of certain types of adamantinoma, basalcelled carcinonia, or rodent ulcer, a structure which possibly justifies the diagnosis of ada-To the pathologist the chief intermantinoma est of these tumors hes in their etiology and pathogenesis Fischer accepted the view that the tumor had its origin in a fetal cell rest and Hawksley also postulate a fetal cell rest, but lay a little more stress on the trauma as stimulating this rest into growth. Ryrie dislikes the idea of fetal cell rests in positions in which they are adequately explained on embryological grounds, and accounts for the growth on the theory of "thwarted repair" He claims that there can be considerable laceration of the subcutaneous tissues skin appendages, and periosteum without breach of the skin surface, and it is this dragging, with consequent deep laceration, that is the peculiar feature of trauma in this region, entailing subcutaneous and periosteal hemorrhage and a long process of organization and ossification. We know that thwarted reparative growth at the edge of a chronic ulcer passes over into neoplastic growth, and that thwarted hyperplasia in liver cirrhosis passes into neoplasia Similarly, the reasonable explanation of adamintmoma of the tibia appears to be that in the region of the ossifving hematoma thwarted repair ultimately passes over into tumor growth. That the exact reaction or environment necessary to maintain a growth stimulus and yet prevent repair will rarely arise, and then only by the fortuitous coincidence of many factors, fits in with the rarity of these tumors. It removes the tumor from the position of a mysterious and isolated entity into the great group of tumors which have chronic irritation as an important factor in their Ryrie further suggests that we should etiology look upon these tumors as arising certainly from trauma, but also as a peculiar response to trauma in persons congenitally predisposed to such reac tions If this theory is correct it suggests that some other cases of epithelionia following trauma may be explained similarly—British Medical Journal December 3 1932, ii, 3752

Allergy and Some Allergic Diseases -W Langdon Brown describes allergy as an unusual response to an ordinary stimulus, which, though marte and familial, is yet modified by conditioned Every known protein contains a lustadine fraction Break off a CO2 molecule from this and it becomes a powerfully toxic substance, histanine, which can produce all the phenomena These phenomena are possibly due of allergy to an inborn error of metabolism characterized by lack or shortage of a particular intracellular ferment-histaminase Part of the reaction depends upon the nervous response W E Dixon (1917) showed that after the vagus to the heart and been stimulated a substance could be extracted from the heart muscle which was antagomized by atropine. It seems as if atropine prevents the liberation of an inhibitory hormone which is usually secreted in answer to vagus This accords with the well-known stimulation effect of atropine in checking other secretions Dale observed that adrenalme directly antagonizes Here we are upon the threshold of the mystery regarding the interrelations of nervous and chemical mechanisms Dale's observation explains why adrenaline is by far the most effective treatment in an allergie crisis, for it both nentralizes lustamine and stimulates the sympathetic nerves to smooth muscles, such as those of the bronch, uterus and intestine These observatious show further how it is that the psychie state can modify allergic manifestations great function of the parasympathetic or extended vagus may be described as promoting the assimilation of suitable and the rejection of unsuitable material. In allergy the response usually takes the form of trying to evict the invading foreign protein by every possible means, but if this is inadequate the cell will die rather than surrender its chemical individuality

In discussing the relation of purpura and especially arthritis purpura to giant urticaria, Brown states that there is an allergic factor in certain infections and purpura is sometimes a manifestation of this. A patient may have purpura at one attack and giant urticaria at another In this condition Brown has found organisms in the stools similar to those found in Henoch's purpura A typical case of this kind showed B a clchu, which can produce a series of events ranging from intense hemolysis to recurrent attacks of giant urticaria. It has been suggested that some cases of enuresis are due to allergy Here as elsewhere, there is a clear cut antagonism between the sympathetic and parasympathetic nerves Ephedrine, by stimulating the sympathetic, may check enuresis more effectively than belladonna which paralyzes the parasympathetic. In angioneurotic edema and asthma the nervous factor plays an important part. In some cases asthma is purely a psychological problem, in others the toxic factor is the primary thing

the nervous factor being merely the failure of the nervous system to cooperate in getting rid of the toxin. The universal belief in the efficacy of beliadonna in asthma finds its justification in the paralyzing effect of the drug on the parasympathetic. The importance of restoring impaired endocrine balance in cases of allergy should not be overlooked.—Practitioner, December, 1932, exxix, 774.

A Skin Carcinoma Regarded for Two Years as a Varicose Nodule.—A case is reported by C. Lang in the Münchener medizinische Wochenschrift of November 4, 1932, which apparently has no counterpart in the literature. A painless bluish swelling of the right lower leg above the internal malleolus was mistaken by several physicians for a varicose nodule on account of its striking resemblance to a dilatation of a vein. Not until the nodule was extirpated and the histological findings reported was the lesion recognized as a skin cancer by its numerous epithelial proliferations, which in some places exhibited concentric formations with cornification and manifestation of parakeratosis. The whole course of the disease and the clinical findings pointed to a local venous dilatation, that is, a varicose nodule the skin of which presented an inflammatory appearance. The entire external part of the bluish tumor consisted of disintegrated red blood corpuscles which owed their origin to hemorrhages caused by the carcinoma. It is true that there are cases in the literature in which varicose nodules have been mistaken for tumors, and there are many observations in which their differential diagnosis from tumors in the region of the saphenous vein has been difficult; but in all these cases a tumor had been thought of before operation, while here the case was reversed, and what was clinically a varicose nodule proved upon histological examination to be a malignant tumor. Relations between varices and carcinomas are as a rule not observed until processes of ulceration of dilated venous regions set in, and a carcinomatous disintegration of a leg ulcer appears. The author believes this is the only case in the literature in which a nonulcerated varix has been described in connection with a carcinoma. That surgical extirpation is the safest way of handling an isolated venous dilatation is emphasized by the possibility of a carcinoma appearing clinically as a varicose nodule.

Infected Wounds of the Limbs and Syndromes of Syringomyelia.—According to B. Pomme and M. Daniel, the etiology of syringomyelic syndromes, which is of great importance in forensic medicine, has been the object of two lines of research, the anatomopathological and

Taking only the latter into considthe clinical. eration, the authors have concerned themselves particularly with infections, especially small infected wounds of the extremities, accompanied by inflammation or prolonged suppuration, which may be followed by grave syndromes. The history of the infectious episode is in brief as follows: On the palm of the hand or the sole of the foot there has been an infected wound of only slight dimensions transversely and in depth only moderately penetrating. Cicatrization has been effected first upon the surface, more or less rapidly and completely. Meantime microbes of anærobic tendency have succeeded in vegetating under the surface, and have produced toxins in sites difficult to reach. These have impregnated the nerve extremities of this territory, silently for the most part, but in a slow and prolonged manner. Occasionally the evolution is more rapid. and the result is a phlegmon. In any case, torpid inflammation, long suppuration or a phlegmon has induced a veritable imbibition of the peripheral nervous tissue, which bears a certain analogy to tetanic intoxication. The interval separating this period from the appearance of the syringomyelic syndrome is characterized by an unbroken series of manifestations finally orienting toward syringomyelia only after many months or years, as much as 20 years in one case on record, always with increasing severity. An eventuality against which the medicolegal expert must be on guard is that the infection which appears to have been primary is in reality only an epiphenomenon grafted upon a syringomyelic syndrome already in course of evolution. After a positive diagnosis and differential diagnosis of the clinical syndrome, the expert must satisfy himself with regard to the following facts: (1) The prior existence of the infectious process; (2) a topographical correspondence between the site of the primary infection and the zones of secondary manifestations of syringomyelia; (3) an unbroken succession of symptoms. A few of the less classical points in diagnosis are the remnants of lesions, the somewhat indefinite limits of radicular systematizations, absence of hyperalbuminosis, the ease with which lipiodol passes, and even the slow and irregular evolution of the syringomyelia, in contrast with other causes of medullary changes. If these conditions are fulfilled, one is justified in assuming that the axis cylinder of the nerve has been affected by an ascending neuritis. Such cases are, as a matter of fact, quite rare, and presuppose an ensemble of circumstances that do not seem to depend solely upon the microbe (toxins proceeding in a neurotropic direction), but also upon a soil that has been rendered fragile primarily or otherwise. -Journal de Médecine de Lyon, November 20.

LEGAL

NECESSITY FOR MEDICAL TESTIMONY IN MALPRACTICE ACTIONS

By LOREN J. BROSNAN, ESQ. Counsel, Medical Society of the State of New York,

A malpractice action illustrating the attempt which patients sometimes make to spell out a cause of action against a physician by the use of lay testimony, was recently decided by the highest court of one of our southwestern States. The case was instituted on behalf of a minor about nineteen years of age. Fifteen years previously it seems that the defendant, who specialized in ear, nose and throat work, had operated upon the boy for the removal of his tonsils. The claim was made that at the time the defendant performed the tonsillectomy he removed also the uvula, palate and tonsillar pillars and, in addition, failed to properly diagnose and treat a condition of adenoids and suppurating cars from which the child was suffering at the time. The complaint charged that as a result of the improper treatment the child had lost his powers of speech and hearing, and as a further result that his mentality was impaired so that although he was nineteen years old his mental development was that of a child of six years of age. The physician interposed a general denial to these charges and also contended that the boy's defects of speech and hearing were congenital as he had always been practically deaf and dumb since the time of his birth.

On the trial of the case the plaintiff's condition during the fifteen-year period was established by lay testimony. No doctor was called to testify that he knew from observation the condition of the boy's throat during the long period of time. In order to bridge the gap between the operation by the defendant and the time when suit was commenced, the mother of

the boy testified in part as follows:

"Ever since the operation why the phlegm has collected in his throat and at night gets out on his pillow.

"Q. Did that ever happen before the opera-

tion? A. No sir, it never did.
"Q. State whether or not that condition began right after the operation. A. Yes sir, right after the operation.

"Q. Mrs. S-, has Carlton outside of this condition of phlegm you describe, has he ever had any kind of disease of his throat of any kind? A. No sir.'

Counsel for the defendant strenuously objected to the last question on the ground that the witness, as a lay witness, was incompetent to so testify. The court overruled this objection. A similar ruling was also made when the boy's father was asked the following question:

"Q. Has Carlton at any time had any apparent; outside of adenoids and tonsilitis, has Carlton at any time had any apparent disease of his month or throat?"

Three doctors were called as experts on behalf of the plaintiff, each of whom had examined the boy. One of the said doctors stated that from his examination of the boy's throat he was able to state that the condition he observed, namely, obliteration of the uvula, palate and tonsillar pillars, was due not to disease or atrophy, but to the tonsillectomy performed over fifteen years before by the defendant. He said that the nature of the scars was such that he could make the statement with certainty. The other two experts called by the plaintiff were more cautious in their testimony, however, and each said that the conditions which he had observed might have been due to any one of several things, either congenital defects existing since birth, traumatic injury, operation or disease causing a sloughing or atrophy. The three doctors testifying against the defendant were each asked a hypothetical question of which an essential portion required the assumption that the boy had during the fifteen-year period suffered no disease of the ear. head or throat. Each of these doctors answered that, assuming along with other facts, the truth of the testimony of the parents that the child had suffered from no disease, they could state that the unfortunate condition of the child's month and throat at the time he was examined by them was due in their opinion either: (a) to the use of improper methods or instruments during the tonsillectomy; or (b) to negligence or lack of care during the tonsillectomy; or (c) to lack of proper knowledge and skill to perform the tonsillectomy,

On the strength of said testimony the case was sent to the jury and a substantial verdict was brought in in favor of the plaintiff. From the judgment an appeal was taken to the Court of Civil Appeals, urging various grounds for reversal.

The Appellate Court carefully considered the record of the trial in the lower court and decided that several points entitled the defendant to a reversal and a new trial. The court concluded that the case was one where the burden of proof was on the plaintiff to prove that the defendant's

operation was the positive cause of the injuries and that during the fifteen-year period none of the various other possibilities which had been stated by the two experts could have existed. In other words the Appellate Court was of the opinion that in this sort of a case the plaintiff was under the necessity of showing by competent proof that the operation by the defendant was the only possible competent producing cause of the injuries complained of. If it was possible that disease, atrophy, trauma or congenital defects caused the condition, then the verdict could not stand. The court ruled that the doctrine of res ipsa loquitur could not be applied to connect up the injuries with the tonsillectomy, for the competent medical proof of the plaintiff's own witnesses had shown that other causes than the operation were possible. The only testimony to negative the existence of the enumerated possibilities and to pin the blame on the earlier operation was the lay testimony above set forth in part. In ruling that the said testimony had been improperly admitted in evidence the court stated the following:

witness cannot testify that a person did not in fact have any disease of the throat or mouth during any given period of time. In the instant case the expert witnesses testified to a number of specific diseases which might have caused the sloughing off or an atrophy of parts of appellee's throat during the fifteen or sixteen-year period in question. They gave none of the physical symptoms or physical evidences of these particular diseases of the throat while running their course, such as might be observed by any person, or especially by the parents of appellee, who constantly associated with him during the period in question. Some of these diseases may have been of an insidious nature and only ascertainable by those engaged as specialists for treatment of such throat diseases. So, if the conclusion of appellee's parents that he had no disease of the throat during the period in question be eliminated as incompetent evidence, then the only remaining part of this non-expert testimony is that of appellee's mother to the effect that continuously since the operation appellee has been discharging phlegm from the mouth and LEGAL

seriously. The said trial resulted in an acquittal, and subsequently thereto the man so examined by the doctor and acquitted in the Justice of the Peace court instituted an action for duringes mining as one of the defendants the doctor and charging him with having improperly compelled him to submit to a physical examination, and without proper cause so conducting the same examination that as a result thereof the plun-

tiff was confined in jail. The constable who had arrested the plaintiff was named as co-defendant

This ease was brought on for trial in the Supreme Court and after all the testimony had been put in the case was submitted to the jury like jury retuined a verdict in favor of the defendants thereby completely exponerating the doctor from all charges that the examination made by him had been improper

ABDOMINAL OPERATION—MALPRACTICE CASE BARRED BY JUDGMENT FOR DOCTOR'S BILL

A surgeon was consulted by a middle aged man with respect to various complaints of intestinal trouble. The doctor examined him and made a tentative diagnosis of appendicitis. The doctor advised an operation and the patient consented. The doctor upon opening the abdomen discovered the presence of a tumor in the ascending colon. He corrected the condition which he found and made a so called sidetracking duct which proved satisfactory to relieve the condition. The wound was closed and the patient improved uneventfully.

Apparently sometime later the patient consulted another surgeon, who found a small sinus at the site where the first surgeon had operated. The second doctor opened the abdomen and found a carcinomatous condition in the ascending colon. He removed the ascending colon completely attaching the stump of the gut to the transverse colon. The man obtained a very satisfactory end result.

The first doctor at the close of his treatment sent the min a bill for his fee, and the patient claimed that said bill was rather excessive and offered to the doctor a settlement of half the amount. The doctor, feeling that his fee was moderate, refused to accept the offer. The doctor was obliged to institute sint in the City Court for the amount of his bill, and the patient defended on the theory that the professional services which he had received were not worth the amount claimed.

After the said action had been pending for several months, an action was instituted against the doctor by the patient in the Supreme Court illeging that the treatment iendered the patient was improper. Thus, of course was the same treatment with respect to which the doctor had several months before sned for his bill in the City Court. The purpose of the Supreme Court action apparently was to delay the doctor's action for his fee for as soon as the doctor had put in an appearance in the Supreme Court action, the patient applied for an order to consolidate the City Court action with the Supreme Court action.

The doctor's personal attorneys who represented him in the City Conrt action, and your Society's coinsel who represented the doctor in the Su preme Court action, united in opposing this application on the ground that the only purpose of the same was to delay the collection of the doctor's bill. The result was that the conrt refused to order the consolidation of the two actions.

The doctor's personal attorneys brought on the City Court action for trial shortly thereafter, and the said case was tried before a judge and jury. After a two day trial in which the value of the doctor's services was challenged by the patient the jury awarded a verdict in favor of the doctor for substantially the entire amount of his bill. Judgment was entered on the said verdict and promptly paid by the patient

Thereafter the attorney for the doctor in the Supreme Court action obtained leave from the court to serve a supplemental answer setting up the facts of the trial in the City Court action as an adjudication of the entire matter and as a defense to the cause of action based upon malpractice A further application was made to the court on behalf of the defendant doctor in the Supreme Court action to compel the patient to reply to the said supplemental pleading. The patient's reply admitted that the doctor had obtained a verdiet in the City Court in his action to recover his fee for professional services but chillenged the contention made on behalf of the doctor that the City Court adjudication amounted to a defense. An application was then made on behalf of the defendant by your Society's coun sel for judgment on the pleadings thereby square ly presenting to the court the question whether a determination of an inferior court in favor of a doctor in his suit for his professional fee amounted to a bar to an action for malpractice The Supreme Court judge who heard the application at Special Term ruled that the City Court judgment did operate as a bar to the action for ninlpractice, and granted the defendant doctor's motion for judgment on the pleadings finally ended the matter in favor of the doctor

operation was the positive cause of the injuries and that during the fifteen-year period none of the various other possibilities which had been stated by the two experts could have existed. In other words the Appellate Court was of the opinion that in this sort of a case the plaintiff was under the necessity of showing by competent proof that the operation by the defendant was the only possible competent producing cause of the injuries complained of. If it was possible that disease, atrophy, trauma or congenital defects caused the condition, then the verdict could not stand. The court ruled that the doctrine of res ipsa loquitur could not be applied to connect up the injuries with the tonsillectomy, for the competent medical proof of the plaintiff's own witnesses had shown that other causes than the operation were possible. The only testimony to negative the existence of the enumerated possibilities and to pin the blame on the earlier operation was the lay testimony above set forth in part. In ruling that the said testimony had been improperly admitted in evidence the court stated the following:

"We are clear in the view that this was error. The decisions uniformly hold that whether a person has a disease is a question calling for professional or expert testimony. Manifestly this rule would extend to any throat disease, and particularly to any disease which might cause the sloughing off or atrophy of the parts of the throat. It is true that a non-expert witness may testify to the presence of disease of an outward nature, or one physically apparent and obvious to any person; or to the non-presence or non-appearance of any physical or outward evidences of disease of a person whom the witness had opportunity to closely observe; but a non-expert

witness cannot testify that a person did not in fact have any disease of the throat or mouth during any given period of time. In the instant case the expert witnesses testified to a number of specific diseases which might have caused the sloughing off or an atrophy of parts of appellee's throat during the fifteen or sixteen-year period in question. They gave none of the physical symptoms or physical evidences of these particular diseases of the throat while running their course, such as might be observed by any person, or especially by the parents of appellee, who constantly associated with him during the period in question. Some of these diseases may have been of an insidious nature and only ascertainable by those engaged as specialists for treatment of such throat diseases. So, if the conclusion of appellee's parents that he had no disease of the throat during the period in question be eliminated as incompetent evidence, then the only remaining part of this non-expert testimony is that of appellee's mother to the effect that continuously since the operation appellee has been discharging phlegm from the mouth and throat, which to the lay mind would indicate that appellee had continuously from the date of the tonsillectomy suffered from some character of throat or mouth disease, the nature and deleterious effect of which only experts are competent to testify."

The court having thus ruled that the vital link in the testimony had been improperly in evidence, ruled that the hypothetical questions had also been improper, embodying as they did the offending testimony. Consequently, the expert opinions that had been put in evidence to the effect that the defendant doctor had been guilty of malpractice were also ruled out.

PHYSICAL EXAMINATION TO TEST INTOXICATION

One evening a physician received a request by telephone call from a member of the local police force to go to the police station for the purpose of making an examination of a certain individual who had just been arrested for reckless driving, driving while intoxicated, and leaving the scene of an accident. The doctor immediately went to the police station and found a person apparently in a state of intoxication.

He made an examination which consisted of taking the man's reflexes, asking him to walk in a straight line, taking his blood pressure and asking him various questions. The answers which he obtained from the man suggested that this person was in a state of intoxication. When asked his occupation he said that he was an actor, whereas in fact he was a lawyer. When asked what his name was, he stated that it was John Doe. When asked if he drank liquor, he stated

that he drank "only as much as you can get at P—'s" (a certain restaurant). The doctor tried the man on five typical expressions for the purpose of testing his speech, and the man managed to pronounce properly three out of the five. The doctor also smelled alcohol on the man's breath. He reported to the police authorities that as a result of his examination his diagnosis was that the man was intoxicated.

Later the case arising out of the arrest came to trial before a Justice of the Peace and a jury of six. The prosecution was not represented by an attorney although the defendant did appear by counsel. The defendant in said proceedings explained in court his conduct at the physical examination by stating that he did not believe that the doctor had any right to examine him and that his replies were merely facetious as he did not take the proceedings in the police station

LEGAL

seriously. The said trial resulted in an acquittal, and subsequently thereto the man so examined by the doctor and acquitted in the Justice of the Peace court instituted an action for damages naming as one of the defendants the doctor and charging him with having improperly compelled him to submit to a physical examination, and without proper cause so conducting the same examination that as a result thereof the plain-

tiff was confined in jail. The constable who had arrested the plaintiff was named as co-defendant.

This case was brought on for trial in the Supreme Court and after all the testimony had been put in, the case was submitted to the jury. The jury returned a verdict in favor of the defendants, thereby completely exonerating the doctor from all charges that the examination made by him had been improper.

ABDOMINAL OPERATION—MALPRACTICE CASE BARRED BY JUDGMENT FOR DOCTOR'S BILL

A surgeon was consulted by a middle-aged man with respect to various complaints of intestinal trouble. The doctor examined him and made a tentative diagnosis of appendicitis. The doctor advised an operation and the patient consented. The doctor upon opening the abdomen discovered the presence of a tumor in the ascending colon. He corrected the condition which he found and made a so-called sidetracking duct which proved satisfactory to relieve the condition. The wound was closed and the patient improved uneventfully.

Apparently sometime later the patient consulted another surgeon, who found a small sinus at the site where the first surgeon lad operated. The second doctor opened the abdomen and found a careinomatous condition in the ascending colon. He removed the ascending colon empletely, attaching the stump of the gut to the transverse colon. The man obtained a very sat-

isfactory end result.

The first doctor at the close of his treatment sent the man a bill for his fee, and the patient claimed that said bill was rather excessive and offered to the doctor a settlement of half the amount. The doctor, feeling that his fee was moderate, refused to accept the offer. The doctor was obliged to institute suit in the City Court for the amount of his bill, and the patient defended on the theory that the professional services which he had received were not worth the amount claimed.

After the said action had been pending for several months, an action was instituted against the doctor by the patient in the Supreme Court alleging that the treatment rendered the patient was improper. This, of course, was the same treatment with respect to which the doctor had several months before sued for his bill in the City Court. The purpose of the Supreme Court action apparently was to delay the doctor's action for his fee for, as soon as the doctor had put in an appearance in the Supreme Court action, the patient applied for an order to consolidate the City Court action with the Supreme Court action.

The doctor's personal attorneys who represented him in the City Court action, and your Society's counsel who represented the doctor in the Supreme Court action, united in opposing this application on the ground that the only purpose of the same was to delay the collection of the doctor's bill. The result was that the court refused to order the consolidation of the two actions.

The doctor's personal attorneys brought on the City Court action for trial shortly thereafter, and the said case was tried before a judge and jury. After a two-day trial in which the value of the doctor's services was challenged by the patient, the jury awarded a verdict in favor of the doctor for substantially the entire amount of his bill. Judgment was entered on the said ver-

dict and promptly paid by the patient.

Thereafter the attorney for the doctor in the Supreme Court action obtained leave from the court to serve a supplemental answer setting up the facts of the trial in the City Court action as an adjudication of the entire matter and as a defense to the cause of action based upon malpractice. A further application was made to the court on behalf of the defendant doctor in the Supreme Court action to compel the patient to reply to the said supplemental pleading. The patient's reply admitted that the doctor had obtained a verdiet in the City Court in his action to recover his fee for professional services, but challenged the contention made on behalf of the doctor that the City Court adjudication amounted to a defense. An application was then made on behalf of the defendant by your Society's counsel for judgment on the pleadings, thereby squarely presenting to the court the question whether a determination of an inferior court in favor of a doctor in his suit for his professional fee amounted to a bar to an action for malpractice. The Supreme Court judge who heard the application at Special Term ruled that the City Court judgment did operate as a bar to the action for malpractice, and granted the defendant doctor's motion for judgment on the pleadings. This finally ended the matter in favor of the doctor.

NOTES NEWS

TRI-STATE CONFERENCE

The twenty-first meeting of the Tri-State Medical Conference was held in the Hotel Chelsea, Atlantic City, New Jersey, on December 20, 1932, with Dr. A. Haines Lippincott, of Camden, President of the Medical Society of New Jersey, in the Chair, and eighteen representatives present. Those from New York were: Drs. W. D. Johnson and G. M. Fisher, Past Presidents of the State Society; Dr. J. S. Lawrence, Executive Officer; and Dr. John A. Hartwell, President of the New York Academy of Medicine.

The general subject of the conference was national health insurance, with particular reference to the report of the national committee on the Costs of Medical Service, which was made public on November 29, 1932. The stenographic report of the proceedings of the Tri-State Conference fill 135 typewritten sheets.

Dr. Henry O. Reik, Editor of the Journal of the Medical Society of New Jersey, gave a paper in which he described the English system of health insurance as he saw it during a tour of

England in the summer of 1930.

Dr. T. C. Routley, Toronto, General Secretary, Canadian Medical Association, gave an address on "National Health Insurance in England and Canada." He said that each Canadian Province is autonomous in its control of medical practice, as is a State of the United States. following descriptions which he gave concerning investigations in several Provinces are news items of interest to physicians of New York

British Columbia has had a Royal Commission which has collected information and opinions for

three years. This commission reported:

"Compulsory health insurance is proving to be an important and valuable factor in the improvement of health. The people of British Columbia are in favor of compulsory health insurance and the maternity benefit scheme. The British Columbia Medical Association decided to support the scheme, provided it included certain safeguards such as free choice of the doctor, compulsory entrance for all wage earners under a certain figure, and payment of the doctors."

"The figures indicate that the cost of the service would be much greater than its proponents estimated, and it is doubtful that the Province will be able to introduce the measure for a

"Alberta has a government commission which made inquiry into the system of State Medicine,

"Under state medicine there will be only as

many physicians, druggists, and nurses as are needed to do the work well. There will be no cults or isms. The health service will reach every family in the nation. Every community will be a part of some health district served with all that medical science has to offer. Research work will be a part of the individual health service. There will be no money profit. New ideas will be tested, and, if found of value, added to medical science. Doctors will be paid liberal salaries and will do their best to secure advancement in the service."

"People will be taught to care for their bodies. In ill health they will be sure of attention and thus relieved of that sort of anxiety. Periodic health service will enable doctors to practice preventive medicine, which will eliminate very largely the use of drugs."

"Health activities will continue and the medical service will have full public confidence because the economic interests of the doctor and patients

will be identical."

"Saskatchewan has 301 municipalities, 75 of which have nunicipal or per diem physicians who are hired by the locality to look after all the illness in that locality. If he is a whole-time man, that is his income. The salary varies from \$3,000 to \$6,000, raised by taxation."

"Manitoba has 500 to 600 doctors whose economic condition is so bad that they are demanding that something be done for them. A conference will soon be held between the government authorities and the doctors, looking to some arrangement whereby the doctors will be subsidized."

"Ontario is the scene of a unique experience. in that the Cabinet has issued an 'Order in Council,' that relief for unemployed persons shall include medical services and medical supplies; but payment for the services shall not exceed one-half of the standard medical charges." (Dr. Routley then described the opinions of thoughtful doctors regarding the best methods of administering the proposed relief measures, and they agreed generally with the methods adopted by some medical societies in New York State in dealing with the County Welfare Commissioners in regard to bills for the treatment of the indigent.—Editor's note.)

"Quebec also has a Royal Commission investigating health or 'social' insurance. The physicians seem to favor some form of social insurance, but they say that they do not want the English panel system."

Dr. Routley said in closing:-

"We cannot divorce the business from the professional side of medicine today, unless we hand over all of the business side to some third party;

against."

Dr. John A. Hartwell, President of the New York Academy of Medicine gave an address on the subject, "A résumé of the work of the Committee on the Costs of Medical Care," and compared the recommendations in the majority report with those made by the minority.

Dr. Arthur C. Morgan, of Philadelphia, one of

the signers of the minority report of the Committee on the Costs of Medical Care, described some of the steps taken by the majority and minority members in writing and revising their reports.

Dr. R. G. Leland, Chairman of the Bureau of Economics of the American Medical Association, discussed the report of the Committee on the Costs of Medical Care with special reference to practice by medical groups, and insurance schemes to provide for hospital care for the insured.

ORANGE COUNTY PUBLIC WELFARE COMMITTEE

The account of the annual meeting of the Orange County Medical Society held on December 13, 1932, which was printed in this Journal of January 1, 1933, contained a brief reference to the annual report of the Welfare Committee on the payment of bills for the medical care of the indigent. The physicians of Orange County have developed plans and methods which are somewhat different from those in other counties, and yet are adapted to the peculiar conditions of their own County of Orange. An abstract of the report is therefore printed for the information of physicians and welfare commissioners of other counties.—Editor's note.

Welfare cases can be classified in two groups: (1) Those which are treated in the home or from the physician's office; and (2) those which are treated in a hospital or other institution.

In considering the first group, it was found that certain municipalities have made special arrangements for doing this work on a contract basis. This condition obtains in two of the cities and also in one or two towns. In most of the towns, however, the work is being done by the physicians of the locality on a fee basis in cooperation with the local welfare officers with varying degrees of satisfaction. It would seem that the degree of cooperation between welfare officer and local physician has improved during the year, and has to a large extent depended on whether or not the physician concerned had the time and patience to follow the procedure laid down in the law of asking the welfare officer to investigate, and where indicated, authorize treatment under the welfare law.

When your committee came to investigate the question of hospitalized welfare cases, a somewhat different situation was found. When the law became active, representatives of the hospitals in the county met with a committee of the Board of Supervisors, and a hospital rate of \$5.00 per day was agreed upon. It was considered advisable by both committees to establish a uniform rate throughout the County, and the rate established was slightly under the average per diem bed cost. It should be pointed out that hospitals

charge all the way from nothing to private patient costs, and that this welfare rate is evidently meant to more nearly approach actual cost than the so-called ward rate. The hospital welfare situation, however, has been very much confused by the fact that one or two hospitals in the County have classified welfare patients as ward patients, so far as medical treatment is concerned. The ward rate is, of course, a semi-charity rate and varies from \$3.00 per day in one or two hospitals in the County to \$3.50 per day in St. Luke's, Newburgh, and \$4.00 per day in the Horton Memorial at Middletown. This classification is of considerable importance to the physician, because the ward rate usually marks the dividing line between where the attending physician may charge for his services and where he gives his services gratis.

During the early years of the Compensation Law, this same condition obtained, and many hospitals continued to classify compensation cases as ward patients and thus precluded physicians from rendering a bill to which they were legally entitled. It would seem that a somewhat similar situation now obtains in at least one hospital in the County with respect to welfare cases. Although this is a hospital problem, it also presents a problem in the practice of medicine and would seem to be a fit and proper subject for discussion in this Society.

At the present time your committee finds that lospitalized welfare cases are being charged for medical and surgical services in the following hospitals in the County: St. Francis and Deerpark, Port Jervis; Horton Memorial, Middletown; The Goshen Hospital; The Warwick Hospital; The Tuxedo Hospital; and to a limited extent, The Cornwall Hospital. It was found that many of the hospitals already have made special arrangements for those welfare cases which originate in the municipality where the hospital is located. These cases are not subject to competitive bidding on the part of the other hospitals in the County and do not need to be considered at the present time. Your Committee feels, however, that in order to eliminate unfair

and dangerous hospital competition, it is essential to maintain the principle of uniform hospitalization charges for those cases which do not originate in the municipality where the hospital is located. As it is the total hospitalization cost which is of interest to the welfare officer, it is apparent that to achieve this, there must also be uniform charges for medical services. Recommendations to this effect were made at the last regular meeting of this Society and following this report, the following resolution was adopted by this Society:

1. That there should be uniform medical and surgical charges for the treatment of all County Welfare cases in the hospitals of Orange County.

2. That the Public Welfare Committee be asked to submit a schedule of such charges to the Society at the Annual Meeting in December.

3. That if this schedule of medical and surgical charges for welfare cases in hospitals be adopted by the Orange County Medical Society, it should then be submitted to the Medical and Surgical staffs of each hospital in the County with a view to obtaining uniform hospital charges for all County welfare cases.

4. That such schedule is not meant to apply to cases originating in the municipality in which

the hospital is located.

On November the 23rd, an open meeting of the Welfare Committee was held, to which each hospital in the County was invited to send a representative of the medical staff. In addition to the committee members, the medical staffs of the following hospitals were represented: St. Luke's, Newburgh; Cornwall, Goshen; Warwick; Horton Memorial, Middletown; and Port Jervis. At this meeting it was generally felt that, if the physicians would agree to attend hospital welfare cases at approximately one-half the prevailing charge for private patients, they would still be making a considerable contribution to community welfare work. It would seem that such a rate could be accepted as fair and reasonable by the hard pressed public official and would be of at least some help in meeting the overhead charges of the hard pressed physician.

It was the opinion of those present at this joint meeting that it would be desirable to have the hospital render a joint bill which included

both the hospital charges and the physician's charges. From the standpoint of the welfare officer, it should be pointed out that he is already paying medical bills directly to the physician for hospitalized cases in the majority of hospitals in the County.

The advantage of this proposed scheme to the welfare officer is that it will prevent over-charging on the part of any physician who might be so inclined, inasmuch as the physician's charges can be estimated in advance and become a matter of record in the hospital office. This matter calls for active cooperation between hospitals, physicians, and welfare officers, and it is in the hope of furthering such cooperation that these recommendations are made to this Society:

In medical cases and non-operative surgical cases the charge for medical services shall be \$1.50 per hospital day, irrespective of the num-

ber of daily visits.

The charges for operative surgical cases shall be fifty per cent of the prevailing charge for private patients, this charge to include aftertreatment while the patient is in the hospital.

The surgeon's fee shall include that of his

assistant.

The charge for anesthesia shall be \$5.00 in cases under one hour of operation, and \$7.50 in cases over one hour.

A surgical fee of \$100 shall be the maximum for any major operation, including the assistant's fee and after-treatment.

The charge for medical and surgical attention at an uncomplicated confinement case shall be \$25.00; and for an instrumental case, \$35.00.

Vie recommend that this schedule be worked one in greater detail during the next year; and that conferences be arranged with the Economics Committees of adjoining counties, with a view to evolving a schedule of charges which will be uniform for the counties of Orange, Sullivan, Ulster, and Rockland.

WILLIAM J. HICKS, Chairman, EARL C. WATERBURY, J. EMERSON NOLL, T. D. MCMENAMIN, W. W. DAVIS.

COLUMBIA COUNTY

The Board of Supervisors of Columbia County met on December 21, 1932, and voted to establish a County Department of Health, for the entire county, including the City of Hudson. Columbia therefore follows the lead of Suffolk and Cortland Counties in including all the area of the county in its department; while the other two counties Westchester and Cattaraugus—exclude some of the cities.

The physicians of Columbia County have supported the county department plan and have made constructive suggestions for its organization and administration; and it was the attitude of the county society that led the Board of Supervisors to investigate the plans and establish the department.

The movement for a county health department may be traced back to October 1, 1929, when the

County Medical Society voted to approve the employment by the Board of Supervisors of two public licalth nurses under section 2b of the law providing state and

On December 15, 1930, the medical county appointed a committee to urge the Board of Supervisors to give due consideration to the wishes of the society in regard to the personnel of the nurs-

ing committee

On May 6, 1931, a committee of the County Society was authorized to analyze conditions in the county in regard to the feasibility of forming a county licalth department. After a lengthy discussion concerning the cost, requirements, personnel and duties of such a County Health Department, the following motion was adopted

Moved, that this County Society go on record as in favor of the establishment of a County Health Department, to include the entire County, under the provisions of the present State Aid Law applying thereto, on the condition that four of

the members of the County Board of Health be appointed from a list of its members, selected by the County Medical Society, and also that the County's share of the expense shall not exceed the present cost of administration of Health activities in the County

On October 7, 1931, the Society discussed the method of selecting the physician members of the proposed Board of Health. It was finally decided that the Medical Society should mominate eight physicians from whom the Board of Supervisors should choose four to be members of the Board of Health if the County Health Department should be established

For over a year the physicians quietly asserted their influence in favor of a county health department, and their efforts were rewarded on December 21, 1932 with a favorable vote by the Board of Supervisors

111 NRY C GAISTLE Secretary

JEFFERSON COUNTY

Abstract of a paper on Dr. Samuel Guthrie 1782 1848 read before the Jessesson County Medical Society by Charles C. K. Phelps, M.D., Sacket Harbor, N. Y. on December 15, 1932

Dr Samuel Guthrie, who practiced medicine in Sacket Harbor for thirty years was an outstanding physician, inventor, and manufacturer, such as one associated with a great city The Guthries were Scotch Covenanters, one of whom suffered martyrdom in 1661, while others emigrated to New England At the time of the Revolution a Guthrie and his two sons practiced medicine in Lenox, where a grandson, Dr Samuel Guthrie, was born in 1782 This Dr Guthrie studied medicine with his father and later in the College of Physicians and Surgeons in New York, and in the University of Pennsylvania He served in the War of 1812, and began private practice in Chenango County, New York, but in 1817 he moved to Sacket Harbor and was extensively engaged in the manufacture of vinegar and alcohol by processes which he invented and developed He made sugar from potato starch, and induced a friend Captain Potter to manufacture it on a large scale, not knowing that the product was glucose

He manufactured chlorate of potash, and apphed it in the manufacture of a priming powder which he demonstrated by firing a eaninon in Madison Barracks, using a fiammer to ignite it the sarcastic remark of an officer that soldiers cannot earry hammers to war, led him to invent a percussion lock A representation of Dr Guthne firing the cannon appears on the seal of the Jefferson County Historical Society

Dr Guthrie was as original and praetical in medicine as in the manufacture of chemical prod uets He was the first to use vaccination in Jef ferson County, and gained great fame by his success in preventing smallpo. He was one of the carliest persons to experiment with anesthetics. In a letter writen to his daughter on February 9, 1848, he says.

"I could have made a fortune if 1 had gone to New York as 1 was urged last fall, by making sweet whisky which you remember taking when suffocated with chareoal. You see it is called chloroform and the papers are beginning to give me the credit of discovering it. I made the first particle that was ever made and you are the first lauman being that ever used it in sickness. This likely to prove the greatest discovery in medicane the world ever siw. By breathing it a few seconds the person falls apparently into a sweet sleep, when breasts, legs and arms may be cut away, painful labors ended and all without pam or injury."

In this same letter to his daughter he tells of the death of his son, an officer in our army serving with troops in Mexico who was wounded in the knee and after two amputations of the leg without an ane-thetic lingered a month and died. When hearing of the musthetic properties of the medicine he tried it on a cat which succumbed. The second cat lived. He then tried it on his colored servant which was very nearly fatal. The first actual use of chloroform as an anesthetic was upon a soldier at Madison Barracks who hild a leg amputated by Dr Guthrie.

9

THE DAILY PRESS

A UNIVERSAL LANGUAGE

Doctors are popularly supposed to understand Latin and to converse in it. That was the universal language of physicians and all other educated persons up to a century or two ago, the result being that a student could wander all over Europe understanding the teaching in all the Universities. High School students spend time enough on Latin to be able to speak and understand simple Latin, if it were taught as a living tongue.

Many attempts have been made to invent a simple language, but none have succeeded; but English is being spoken by more and more people, and seems likely to become a world-wide language.

One difficulty with English is its great richness in synonyms. The large dictionaries contain hundreds of thousands of words, but less than one thousand are sufficient for a child of six or eight years.

The New York Herald Tribune of January 3, describes what Professor C. K. Ogden, of Cambridge University, England, calls a "Basic English" which he proposes as a universal language, whose value is that its roots are already understood by millions of people all over the world. The article says:

"Basic English was formulated in 1928, Mr. Ogden said, and is now in the state of being adapted to different countries, since each nation must be taught in its own language, and the grammars made 'foolproof.'

"He and a group of scholars, who are working with him throughout the world believe it will become 'the universal language of radio, the talkies, commerce and science.' There are already phono-

graph records, sketches, and even novels in basic English.

"'Basic English,' he said, and added that he was now using Basic English, 'is an attempt to give to every one a second or international language which will take as little of the learner's time as possible. It is a system in which everything may be said for all the purposes of everyday existence; the common interests of men and women, general talk, news, trade and science. To the eye and ear it will not seem in any way different from normal English, which is now the language of 500,000,000 persons.

"It is an English in which 850 words do all the work of 200,000, and has been formed by taking out everything which is not necessary to the sense. "Disembark," for example, is broken up into "get off a ship." "I am able" takes the place of "I can"; "shape" is covered by the more general word "form"; and "difficult" by the use of "hard." By putting together the names of simple operations—such as "get," "give," "come," "go," "put," "take"—with the words for directions like "in," "over," "through" and the rest, two or three thousand complex ideas, like "insert," which becomes "put in," are made part of the learner's store."

"Mr. Ogden divides his 850 words into four main groups—names of operations, names of things, names of directions, and names of qualities. There are 600 names of things, 400 general, such as 'adjustments,' 'experience,' 'month,' and 200 picturable, such as 'boat,' 'potato' and 'street.' Then there are 150 words for qualities—the adjectives. The vocabulary includes cats and dogs. but no giraffes."

FOUNDATIONS

The New York Herald Tribune of December 28 has an editorial on "Foundations," inspired by a report of the Twentieth Century Foundation on the 206 other known endowments which are organized for administrative purposes and which control funds amounting to over seven hundred and seventy millions of dollars. The editorial says:

"Foundation grants have declined 23.7 per cent in 1931 as compared with 1930. This is almost exactly in the same proportion as the decline in national income. But more important is the shift noted in the flow of their largesse. Though medicine and public health continued to receive much the largest proportion of donations, or 31.4 per cent of the grand total, with education in second place (24.9 per cent), the disbursements for social welfare showed a gain of from \$1,861,450 in 1930 to \$3,367,399 in 1931. 'This charge,' says the report, 'was undoubtedly due to the immense increase in the demand for immediate relief because of the depression.'

"Other increases are attributed to the same influence. Grants in the field of social sciences showed a gain of 45.1 per cent, in that of economics 28.8 per cent. Unfortunately, or so the Twentieth Century Fund views it, the amounts involved in the latter case were negligible.

"Only eighteen of the 102 foundations supplying adequate data showed an interest in economics. Only eight displayed an interest in government. The grants in these fields amounted to 1.5 and 1.6 per cent of the total respectively. Other fields of interest which show a surprisingly small percentage of the whole are child welfare, with 2.3 per cent of the total; individual assistance, with 3.4 per cent; the lumanities, with 1.5 per cent; and, most surprising of all, social welfare, which, in a year when relief measures are headlined in the newspaper's every day, reached only 6.4 per cent of the total of all fields put totogether."

"This is salutary comment. No doubt in many if not most instances the deeds of gift establishing these trusts render them relatively powerless to change the objects of their benefaction. However, an effort to do so might discover a greater elasticity than seems at first apparent. In the meantime the public will continue to regard the great good they do with the gratitude it deserves."

The New York Sun of December 27 supplies the following additional information:

"The Twentieth Century Fund was created in 1919 by Edward A. Filene to furnish a medium through which he might make his public gifts most effective by submitting their distribution to the balanced judgment of a group rather than the personal decision of an individual." The activities of the Twentieth Century Fund are centered almost entirely in the field of economic progress.

"The Carnegie Corporation heads the list of the twenty largest foundations with a capital of \$161,000,000. The Rockefeller Foundation is second with assets of \$143,000,000. Together these two organizations represent about 40 per cent of the total capital of all reporting foundations report-

ing to the Twentieth Century Fund.

"The largest sum given away by any foundation was contributed by the General Education Board, one of the Rockefeller group. It disbursed \$16,-000,000. The next largest sum was \$13,000,000, given away by the Rockefeller Foundation.

"The Carnegie Corporation was third with \$5,-000,000. These three foundations contributed about two-thirds of the total paid out by the 102

foundations.

"The General Education Board at that gave away 47 per cent less than it did the year previous. The Rockefeller Foundation's decrease was 19 per cent, while the Carnegie Corporation increased its gifts by 19 per cent. It was one of four to show increases in disbursements."

THE FAMILY DOCTOR

The *New York Times* of December 19 has the following comment on the relation of the family doctor to the Costs of Medical Care:

"In his annual report to President Butler, Dean Rappleye of Columbia's School of Medicine adresses himself to medical economics—a question recently considered by the Committee on Medical Costs. He warns against adopting any program that endeavors to reduce professional services to mere terms of economics and organization. Physicians have always insisted that the practice of medicine is not only a science but an art. It follows that the 'art' must suffer if a patient is treated as if he were merely a living machine.

"Medical art finds expression in the personal relationship between physician and patient as well as in skill and knowledge. Hence the pleas recently heard on behalf of the old-fashioned family physician. He knew the whims of Aunt Sarah and the aches of Uncle Joe. What he lacked in special knowledge he more than made up by his personality and the confidence that he inspired.

He embodied 'the attributes of friend, priest and physician,' as Dr. Squier aptly put it in his recent presidential address before the American College of Surgeons. Contrast human sympathy in sickness with the mechanical routine inseparable from rigid organization and economics, and we grasp the implications of that 'art' which we are in danger of losing.

"Both the majority and minority reports of the Committee on Medical Costs advocate restoring the general practitioner to his old position. If the ratio of physicians to population were in the United States what it is in France or Germany, we should have some 75,000, Dean Rappleye tells us. Actually we have about 156,000 concentrated for the most part in cities. Solve the problem of finding practice for this oversupply, and we not only solve the problem of medical costs, without resorting to the kind of organization that Dean Rappleye fears, but also enable the old-fashioned family doctor to demonstrate what the Hippocratic oath really means."

BOOK REVIEWS

THE INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practioner's Index. Year, 1932. Edited by CAREY F. COOMBS, M.D., and A. RENDLE SHORT, M.D. Octavo of 658 pages, illustrated. New York, William Wood & Company, 1932. Cloth, \$6.00.

While this issue of the Medical Annual reflects intense activity in all branches of medicine it can hardly be said that the past year has revealed outstanding dcvelopments. Medical literature is to a large extent controversial and so a good deal of it is devoted to discarding methods originally advocated in the heat of enthusiasm. For example,

1. Scarlet fever antitoxin is now recommended with extreme caution as it causes serum sickness in 25% of cases. Whatever good is supposed to accrue from its use is largely problematical.

2. The maggot treatment for osteomyelitis is also in for a fatal attack. The retreating statement reads-"this treatment may be effectual, but it seems unlikely to become popular."

3. Certain tests for diagnosing cancer such as the Bendien test have won ephemeral popularity. The reader may gain an insight into the variety of these tests from

this condensed section of the annual.

4. The subject of focal infection, especially as regards teeth, is in for some heated criticism. Even Rosenow of the Mayo Clinic has become conservative when he now states that "not too much should be expected from the removal of a focus, especially in chronic conditions.

5. The enlarged thymus seems to be losing its momentum as a basis for x-ray therapy. H. K. Pancoast tells us that abnormal width of the thymus shadow on the x-ray is of no particular significance. His statements are well supported by those of other observers.

6. We are also fold that status thymico-lymphaticus has no existence as a pathological entity, and that unexplained sudden deaths should never be attributed to that vague term.

7. Even lysol, so largely relied on as an antiscptic, is now being discarded as a useless and ineffcetive chemical. EMANUEL KRIMSKY.

MANUAL OF CLINICAL AND LABORATORY TECHNIC. BY HIRAM B. WEISS, A.B., M.D., F.A.C.P., and RAPHAEL ISAACS, A.M., M.D., F.A.C.P. Fourth edition. 12mo of 117 pages. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$1.50.

For the busy physician who is in a hurry to find a eomprehensive description of any of the routine clinical or laboratory diagnostic procedures a ready reference guide is invaluable. This condensed handbook describes and interprets these various tests in sixty pages in such a way that the reader is never disappointed. Besides there are some additional pages devoted to height and weight charts, to food values and to other matters to which we must often refer. A book of this type should be within easy reach of the family physician at all times. EMANUEL KRIMSKY.

ORTHOFEDICS IN CHILDHOOD. By WILLIAM L. SNEED, M.D. 12mo of 318 pages, illustrated. Philadelphia, J. B. Lippineott Company, 1931. Fabrikoid, \$5.00.

Pediatrists are constantly confronted with orthopedic problems, in fact they are often the first line of defense in the detection of bone or joint lesions. Treatises on pediatries must of necessity deal with such subjects in a perfunctory manner, and textbooks on orthopedic surgery

offer too much detail for the average physician's need. This volume in the Everyday Practice Series affords a precise clinical picture sufficient for guidance in arriving at a diagnosis of such diseases and deformities as fall within the ever increasing seope of orthopedie surgery. Methods of treatment are plainly stated, and suggestions for office management are practical. Surgical procedures are mentioned and sufficiently outlined to make one's advice to the parent regarding the more serious lesions accurate and authoritative.

The author's aim was to stress simple methods which eould be carried out by the family physician. This he has succeded in doing. It is a good book-worth reading, and full of clinical suggestions which the general surgeon will welcome as well. D. E. McKenna.

PRINCIPLES OF PREOPERATIVE AND POSTOPERATIVE TREAT-MENT. By REGINALD ALEX CUTTING, M.D., C.M., M.A., Ph.D. Quarto of 812 pages, illustrated. New York, Paul B. Hocber, Inc., 1932. Cloth, \$10.00. (Hoeber's Surgical Monographs.)

There is a constant need for a comprehensive survey of nicthods of preoperative and postoperative therapy. With this need in mind, the author has attacked the problem.

In this pursuit, he has covered the general principle, the specific accidents common to any case and the pitfalls of special operations.

The student of surgery is often at a loss to put a true value on various specific procedures. In this treatise these procedures are given a fair value based on experience of the author and the reports in the medical literature. The conclusions often relegate to the diseard many commonly employed procedures or agents.

For the student who is to meet his troubles and for the surgeon who has met them all too often, the text will be of great value. As a textbook to give immediate help to either in his problems, it will be found filled with resourceful measures. It helps one to feel that he has covered all the really useful things that one might do in the presence of vital preoperative conditions and postoperative accidents. In short, it is the latest word on the subject and a book well worth possessing.

ROBERT F. BARBER.

ELECTROSURGERY. By HOWARD A. KELLY, M.D., LL.D., and GRANT E. WARD, M.D. Quarto of 305 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$7.00.

This is a well printed book of 276 pages of text with generous Bibliography, satisfactory index and 382 illus-

trations,—original and very well done.

In the preface, reviewing the advancement of surgery by "leaps and bounds, both in the number of operations done daily, and in the boldness and precision of our technic," Howard Atwood Kelly, who has been in the foremost rank of surgeons since the late sixties, sayselectrosurgery is "destined in no small measure to replace scalpel, ligature and hand contacts with wounds, as well as notably to pare down the number of those listed as the 'inoperables' by skilled surgeons.'

The history of electrosurgery is recounted very faithfully, giving one the real significance of the marvelous progress attained through, not alone medical and surgical works, but by the aid of physicists. Kelly emphasizes the "gratuitous labors" and gives recognition of the elaims of the pioneer. The physics of high frequency currents are probably very thoroughly given in a chapter under that heading. The collaboration of three men,

physicists, assures a very accurate and detailed description.

Clinical and laboratory observations on Histological changes are presented clearly with thorough discussions on electrodeogualation and acusection. Under a sub-title of Laboratory Studies, such worthwhile observations as the following are made: "Metastatic nodules in the intestinal walls or mesentery can be exploded out of existence, the sterilized tissue coagulum disappearing to be replaced by scar tissue;" liver resection by electrosurgery without hemorrhage.

Very valuable are the general principles laid down, covering primary and secondary operations, showing in detail choice of and reason for method applied to soft tissues or bone—biopsy—grafting, etc.

Various chapters cover skin, mouth, ear, throat, thyroid, thorax, breast, abdomen, gynecology, urology, proctology and the central nervous system.

Anesthesia and post-operative care are given much consideration. A chapter is given up to a discussion of irradiation and electrosurgery, contrasting the advantages and the disadvantages. This chapter alone makes possession of this book worth while.

To those of us who read assiduously the works of Howard A. Kelly, this book is again an example of the thoroughness of the author.

JOHN L. BAUER.

THE USE OF LIPIODOL IN DIAGNOSIS AND TREATMENT. By J. A. SICARN and J. FORESTIER. Octavo of 235 pages, illustrated. New York, Oxford University Press, 1932. 'Cloth, \$4.00.

This is a book of 192 pages, profusely illustrated in excellent manner and presenting a very extensive bibliography. This bibliography is probably the most complete on the subject in existence. The work as a while is a most comprehensive study of the use of lipiodol as an aid to diagnosis and as a therapeutic measure. The work starts off with a study of lipiodol itself—its nature, chemical properties, etc.—followed by a most scientific study of the rate of elimination from the tissues or from the body cavities. It is of interest that, according to the authors, lipiodol may remain present up to two years after an injection and is seldont eliminated within one year. The indications and contra-indications of the use of lipiodol as a diagnostic measure in conjunction with radiography are clearly given. The technique of examinations of the spinal canal, sinuscs, male and female generative systems and the broncho-pulmonary system, together with a full description of the instruments used, is set forth in detail.

A discussion of the therapeutic value of lipiodol as an analgesic in painful conditions of the nerves and joints is most completely provided. The workmanship of the book, both as to type used and the quality of the illustrations, is beyond criticism. This book is of value not only to the roentgenologist but also to the various specialists who may use this method of examination to marked advantage.

CHARLES EASTMOND.

Accidents, Neuroses and Compensation. By James H. Huddleson, M.D. Octavo of 256 pages. Baltimore, The Williams & Wilkins Company, 1932. Cloth, \$4.00.

This timely work attempts to analgamate the views of the several neurologists who have interested themselves in the many and varied nervous and mental disorders that frequently follow trauma. The author's own wide experience places him in a unique position to clarify the terms applied by others to the several combinations of symptoms that may follow injury and which are frequently alleged to be the result of the trauma. These mental twists, so closely linked with trauma and therefore in many instances compensable, have been very difficult problems not only for the physician but also for the

lawyers, the ingurance carriers, and the compensation boards.

In this work consideration has been given to the effects of structural trauma, but the author's chief concern has been to bring some order and understanding out of the claotic state in which he finds the present knowledge of the psychogenic disorders associated with or following physical trauma. The subject has been dealt with by chapters on the etiologies, symptomatology, structural pathology, the post-traumatic psychosis, malingering, differential diagnosis, and the prognosis. About one-third of the 216 page treatise has to do with treatment, compensation and prophylaxis. This last mentioned part could be studied in detail to great advantage, particuarly the chapter on treatment.

Every physician who treats injured workingmen should find this book an invaluable aid toward a better understanding of patients whose complaints cannot be explained on a structural basis. JEFFERSON BROWDER.

Human Cancer, By Arthur Purdy Stout, M.D. Octavo of 1907 pages, illustrated. Philadelphia, Lea & Febiger, 1932. Cloth, \$10.00.

In presenting his book, "Human Cancer," the author gives a comprehensive discussion of the development and growth of all types of cancer in the human body. It would be impossible to limit this treatise to one volume if the author had gone into his subject in great detail, and for this reason he has covered the general subject of cancer only. Because of this general treatment, the book is particularly well adapted for the general practitioner and student.

The subject is discussed with great clarity and simplieity, and the result should make a wide appeal not only to the surgeon and surgical pathologist, but also to the general practitioner and the student, as well as to the roentgenologist and radiotherapist. The subject is presented in a particularly well organized and authoritative manner.

It is illustrated with 331 engravings, and includes an appendix by Dr. George F. Laidlaw, covering the Silver Staining of Reticulin and the Differentiation of Cells in Tumors.

FREDERIC DAMEAU.

FUNCTIONAL DISORDERS OF THE LARGE INTESTINE AND THEIR TREATMENT. By JACOB BUCKSTEIN, M.D. 16mo of 265 pages, illustrated. New York, Harper & Brothers, 1932. Fabrikoid, \$3.00. (Harper's Medical Monographs.)

This work, one of a series of books edited by Doctor Harlow Brooks, has been written for the general prac-titioner. The author, who realizes that a dissertation on functional gastrointestinal disorders would hardly fill even a small volume, has taken the opportunity to present much of value in other directions. In Part One he gives a brief, yet comprehensive survey of gastrointestinal physiology and goes at length into the important question of history taking and physical examination. In all the discussions of the so-called gastrointestinal neuroses, the author is very careful to emphasize that a diagnosis of a functional disorder must be made only after the most complete study of the patient has disclosed no lesion accounting for the symptoms. The book is replete with reports of cases treated by the author in accordance with his recommendations, and a careful study of his findings often reveals that an organic condition was the cause of trouble. Part Three, on "Motor-Sensory Neuroses of the Intestine" consists largely of a discussion of organic lesions such as duodenitis, colitis and proctitis with some mention of vagotonia as a cause of colonic disorders. The chapter on constipation is excellent, that on visceroptosis rather poor. As a whole, the book is apt to be misleading to a general practitioner, even though the case histories are illuminating.

January 15, 1933

OUR NEIGHBORS

INDUSTRIAL EXAMINING CLINIC IN WISCONSIN

A proposed clinic for the examination of industrial workmen is described in the Wisconsin Medical Journal for December, as follows:

"A so-called Examining Clinic which will give pre-employment and periodic examinations to potentially upwards of 7,000 employees in the metal trades in Milwaukee, established and financed by the Employers Mutual Liability Insurance Company of Wausau, met with the active opposition of the Council of the State Medical Society of Wisconsin following an all-day special meeting on November sixth.

"The 'Wausau Mutual' is the same company that caused the introduction of a bill in the 1931 legislature providing that nurses in industrial plants should be exempt from the provisions of laws establishing standards for treating the sick and that such nurses might administer not only first aid and apply dressings but might prescribe 'family remedies and medicines allowed by law to be sold without a prescription, for injured or sick employees or to their immediate families.' The bill was killed.

"Under the newly formed Examining Clinic sponsored by the same insurance company, it is the announced intent to form a corporation of employers to hire a physician or physicians who conduct pre-employment and subsequent examinations under the direction of the lay group. Obviously if laymen can group together to hire a physician whose services for diagnostic purposes are to be re-sold, it will likewise be possible for the same group or corporation, or any other group of laymen to enlarge the plan to comprehend other services in treating the sick and injured.
"The announced purpose of the clinic is to

protect employers and the insurance company from the very large bills resulting from an increased number of silicosis claims and to protect the workingmen from silicosis. The clinic is modeled after a somewhat similar organization at Picher, Oklahoma, presently run by mine operators, at which the costs per examination, including blood Wassermann and one 11 by 14 flat x-ray film, have been reduced to under two dollars.

"A long effort by the Council to secure a change in the announced policy of the insurance company so as to permit of the use of local facilities and local physicians capable and willing, under conditions that would not provide for direct control of their work, met with no success. Representatives of the insurance company declared that operation of the clinic would only be successful from the point of view of the information desired by the employer and cheapness of medical service. under the plans announced by them. That the service so organized might be extended to other

cities was admitted to be a possibility.

"Advocates of the plan stated that interested employers insured with the Wausau Company constitute the members of a corporation. This corporation, acting under the financial backing of the insurance company, will sell examinations of em ployees for \$3 each to employers insured with the Wausau Company and at \$5 each to employers not so insured. No information will be given to the employee by the examining physician other than that, when he finds conditions warranting medical service he will state, without disclosing what has been found, that he will be glad to give his findings to the family physician. Employers, on the other hand, will receive a code indicating whether the employee is a desirable physical risk in his present occupation. It was contended that where physical examinations indicated the advisability of the procedure, the man would not be discharged, but his occupation would be 'shifted' to one less hazardous. It was admitted, on the other hand, that comparatively little shifting of employment to avoid dust could be accomplished in most foundries under their present set-up. It was suggested that the plan might actually work out not only to deprive a men of his trade, but to do so with all employers thing advantage of the clinic plan, and upon the result of what might prove to be but a partial physical examination by but one physician. In other words, the usual relationship between physician and patient would be ignored and disregarded for the purposes of the clinic.

"After an all-day session, representatives of the insurance company indicated their willingness to meet with a committee of the Council to iron out basic differences. The Committee found, however, that the company was adamant and as a result the Council voted to support the Medical Society of Milwaukee County and actively oppose the clinic.

"That it was anticipated that the proposed setup of the clinic would bring disapproval of the medical profession was admitted by a representative of the insurance company who stated that the plan had been kept a secret for the better part of a year until it could be announced as being under way. The company had further secured an advisory committee of physicians but in terms of one representative, the main purpose of this committee was 'to sell the profession.'

"To make its opposition effective, the Council (Continued on page 122-adv. xii)

Maltcao Helps Build Resistance

THE PROPERTY OF THE PARTY OF TH

Maltcao, the concentrated food drink with a delicious chocolate taste, fortifies the system and tends to build up bodily resist-

ance to winter colds. This Merckens quality product contains an abundance of calcium, iron, and phosphates. That is why it is not to be confused with ordinary chocolate drinks.

Maltcao is easy to mix with milk or water. Children and grown-ups alike enjoy it with meals or at bed-time. Especially during winter months, when diets are heavier and vegetables less plentiful, Maltcao is a valuable adjunct to the daily diet.

8 oz. sample can to physicians on request Merckens Chocolate Co., Inc., Buffalo, N. Y.

Maltao

(Continued from page 120)

has directed certain officers to bring the positic of the profession to the attention of all affecte including the Surgeon General, the Industri Commission of Wisconsin, and others."

The President of the Wisconsin State Societ Dr. R. H. Jackson, writing on the President Page, says:

"Neither at this conference nor at a later of held in Milwaukee at which were present it President and certain other officers of the insurance company, representatives of the employer and the Council of the State Medical Society, wit possible to convince those promoting the projet that it would be inimical to the best interests the public and especially labor to carry out to plan as outlined to us. Nor were we able to persuade them that among the 850 practitioners medicine in Milwaukee County there were may who were both willing and capable, and equipped with proper facilities to render the desired serving a satisfactory manner.

"When informed that all the facilities of me cine were at their command if they would but them, the reply was, they would not.

"Aside from the question of how such a prest plan affects the public interest and especially t interest of labor, we are here concerned with direct professional problem as to the legal right this proposed corporation of laymen to practi medicine. Even though in this instance such pratice consist solely in the making of a diagnos our tacit consent at this time to the slightest devtion from the basic fundamental principles unda lying what statutory provisions govern the pratice of medicine in this state may well be the etering wedge which will permit the entrance other factors inimical to the public interest and destructive of the ideals of organized medicine

WORKMEN'S COMPENSATION IN UTAH

The relation of the Medical Society to administration of the workmen's compensation in Utah is set forth in the following abstration the December issue of Colorado Medicin

"The malpractice suit assumes an importa place in Industrial Medicine, because in all the States the injured workman has had taken from him by law, the right to bring an action in couragainst his employer, be this employer a minarial railroad, or a manufacturing plant. Now this a very important right. This law is justified by society upon the theory that the remedy law is uncertain, expensive, and hampered lourt delays, while working men's compensation is certain. It is immediate in reaching the injured worker or his family in case of death at the time when it is most needed and at little or no

(Continued on page 123-adv. xiii)

(Continued from page 122-adv. xii)

expense to him, and further he gets it all. But he can and does sue his doctor. The law is silent here.

"It was in 1917 that the working men's compensation law was enacted in Utah. The schedtile of fees paid the doctor at that time together with other restrictions imposed, worked a decided injustice to our medical men. Some of the most experienced physicians refused to care for these cases. The injured men complained to the Commission. They also asked to be allowed to choose their doctor. The Commission employed a physician to serve as a referee. He was a political apointec.

"Various committees from the State Medical Society met with the Industrial Commission and Insurance Carriers from time to time and after much deliberation, extending over a period of years, our present arrangement was brought about.

"The Insurance Carriers and the Commission agreed to an increase in the fees paid physicians provided they could get our best men to serve and at the same time be protected from the unscrupulous doctor who might perchance pad his bill, and also be assured against incompetent services. Here are a few of the listings:

> Old Fee New Fee Schedule Schedule

	acticult	Scucant
Office dressing	\$1.00	\$2.00
House visit, day	2.00	3.00
House visit, night	3.00	5.00
Fracture forearm, one hone.	15.00	35.00
Fracture forearm, both bones	20,00	50.00
Fracture femur	30.00	100.00
Amputation thigh	. , 40.00	100,00
Laparotomy	40.00	150.00
Herniotomy		100.00
Enucleation of eyeball	35.00	60.00

"To take care of this situation, the Utah State Medical Association now furnishes a committee of three experienced physicians which meets with the Commission at the State Capitol every Friday morning. This committee assists the Commission in rating the disability, both temporary and total, of the injured man and in adjusting the doctor's fee which might be in dispute. They also are consulted regarding the contention of the Insurance Carrier.

"This committee of doctors makes a careful investigation in the presence of all parties concerned. They systematically examine the injured man with his clothing removed. He is weighed and measured and given a thorough physical examination. They listen to his story and study the history of the case including x-ray and laboratory findings furnished by the doctor on the case. They discuss the problem with the patient's physician. The Insurance Carrier presents his side of the case, and after all parties concerned

(Continued on page 124-adv, xiv)

tempting, nourishing drink for convalescents

To provide the extra nourishment so essential during convalescence — Coconalt with milk is suggested, at meals and between meals-daily.

Cocomalt is a delicious chocolate flavor food drinkeasily digested, readily assimilated, and palatable even to the very sick. It provides substantial nourisliment at little cost; and is especially useful post-operatively and during convalescence.

Cocomalt is a scientific food concentrate of sucrose, skinmed milk, selected cocoa, barley malt extract, flavoring, and added Vitamin D. Prepared necording to label directions, it adds 45% more protein, 48% more mineral salts and 184% more carbohydrate to a cup or glass of milk—increasing its value more than 70%. It coatnins not less than 30 Steenhoek (300 ADM.) units of Vitamin D per ounce, Cocomalt is

Not only during convalescence, but whenever a high-calone diet is indicated, Cocomalt will be found useful. It is recommended for expectant and nursing mothers, for run-down men and women, for under-nourished children. Comes in 1/2-lh. and 1-lb sizes, at grocers and drug stores. Also in 5-lb. can for hospital use at special price.

Free to Physicians

We will be glad to send you a trial can of Cocomalt without charge. Just mail coupon.

have had their say in the presence of each other, they all withdraw, after which each doctor on the advisory committee gives his conclusions to the Industrial Commission who then make the final decision which is their duty as provided by law.

"This committee of doctors serves without any remuneration whatsoever, and as a result their individual findings are not influenced by private fees. They work as a purely unbiased, scientific body, and their services do not cost the injured man, the Carrier, the Commission, nor the State of Utah, one cent. This service is competent, scientific, and confidential. It is strictly professional and is even better than money can buy.

"To ease the burden on the profession, this service rotates; each doctor is on duty six months. The oldest man in point of service retires, and a new man goes on every two months. A competent x-ray man is included in

this rotating committee.

"Flagrant or unusual cases are appealed to the Council of the State Medical Association, which Council consists of the President, President-elect, and three councillors elected by the House of Delegates. These five men hold a special meeting with the Carrier, the doctor, and the Commission and in like manner iron out the difficulties. So pleased have the state officials been with this service that it has been suggested that the doctors be paid. The profession is of the opinion that if this were done, the service would degenerate into politics and develop a lot of political doctors who would contend for this work as ward-healers do, and the high ideals of our profession be trailed in the dust."

DISTRIBUTION OF MEDICAL SER-VICES IN WISCONSIN

The State Society of Wisconsin has conducted a study of the distribution of Medical services along lines similar to that made by the Committee on the Cost of Medical Care, and the report of the Committee to the House of Delegates fills twenty-six pages of a supplement to the December Wisconsin Medical Journal, the supplement being devoted to the proceedings of the House of Delegates on September 13-15, 1932. The report contains masses of statistics, but the following recommendations are of special interest to physicians in private practice:

"We recommend that the Society disapprove any system which provides a single practitioner to care for the indigent, except such as may be in institutions, for the reason that such a system is not conducive to securing a proper public service."

"We recommend that such component Society

4 New Concentrated Vitamin Products

Vitamin A alone

Name SmacoCaritol Product Nn 505

Description: Catitol 15 a 0 3% solution of carorene in bland oil, providing a safe, palatable and convenient concentration of vitamin A for therapeutic use

Taste: Entire absence of all fishy taste makes it accept able to your patients

Color: Deep red, due to Carotene

Potency: Ten drops contain one thnusand International Units of vitamin A

Dorage Three to five drops daily for infants and young children live to ten drops 'daily for adults

Package: 15 c.c. dtoppet top, protectively-colored bottles, in special cartons to shield it from the light

Cast. Because of its high po tency and the small doses required, it is an inexpen sive source of vitamin A, in spite of the fact that it is the only product contain ing vitamin A alone

Indications. For conditions caused by vitamin A defi-ciency and cured or pte vented by adequate vita min A or carotene dosage

Vitamin D alone

Name: Smaco Concentrared Viramin D Product No 515

Description: This product is Natural Vitamin D, being a highly potent extract of the antitachitic principle of cod liver oil

Taste Palatable and free from objectinnable taste,

Color: Nearly colorless.

Potency: Ten drops are equal tn vitamin D potency to three teaspoons of standard potent cod liver oil

Dosage: Average prophylac no dose, ten drops datly Average curative dose, fif teen to thirty drops daily, depending on severity of case

Package 5c.c and 50c c pto tectively-colored botrles.

Cost: Approximately the same as that current for equivalent vitamin D dos ages of plain cod liver oil.

Indications: For the preven tion of cure of rickets and spasmophilia, and where ever vitamin D thetapy is required, such as tetany and osteomalacia

Vitamins A and D Smaco Cod Liver Oil together

Name Smaco Vitamins Aand D Product No 525.

Description: Smaco Caritol and Smaco Concentrated Vitamin D are combined en this product, providing both vitamins A and D to concentrated form for therapeutic use

Taste Palatable and free from objectionable taste

Color. Red, due to carotene.

Potency. Ten dtops ate equi valent to one thousand International Units of vita min A plus the vitamin D potency of three teaspoons of standard potent cod fiver oil

Dosage: Ten drops or more datly, depending upon in dividual requirements

Package Sc c and 50 c.c pto tectively coloted bottles

Cost: Approximately the same as cutrent ptices for equal dosages of other vitamin concentrates

Indications: Wherever vita-mins A and D are required together in palarable form and small dosage

Name *Smaco Cod Liver Oil (with Carotene and Con centrated Vitamin D) Prod uct No 510

Description, A high grade cod liver oil fortified with vita min A of vegetable origin (carotene) and natural vita min D described in the second column

Faste: Although carotene is not a flavoring agent, never-the less the addition of carotene noticeably tm proves the flavor

Color: Deep red, due to carotene it contains

Potency; One teaspoon is equivalent in vitamin D potency to three teaspoons of standard potent cod livet oil plus 1,000 Inter-national Units of vitamin A per teaspoon in addition to the original vitamin A potency of the oil

Dosage. One terspoon daily for average individual needing vitamins A and D

Package, Four ounce pro rectively-colored bottles packaged in special cartons to shield from light

Cost. Apptnximately one half as much as the equivalent amounts of vitamins A and D when purchased as plain cod liver oil

Indications Wherevera more palatable, concentrated cod liver oil is indicated (Only one-third as much is re quired as plain cod liver oil)

* This product is the Smaco Cod Livet Oil with Carotene announced in September further improved by the addition of the new Columbia Zucker natural vitamin D

New Vitamin Therapy Possible

Up to this time it has not been possible to prescribe vitamin A plane as in cases where vitamin D as not required or is already supplied by sunshine, ultra wielet light, viosterol, etc. Smaco Carrol makes possible the administration of Primary Vitamin A in drop doses, thus permitting the physician to regulate the dosage to meet individual requirements

Smaco Vitamin D is natural vitamin D It is not an irradiated oil and not a cod liver oil concentrate but rather a highly potent extract of the antirachine principle of cod liver oil. It is produced for therapeuric use by methods (Zucker Process) developed in the department of Pathology of the College of Physicians and Surgeons of Columbia University

It now becomes possible with these new Smaco concentrated vitamin products in prescribe vitamin A slone, vitamin D alone, or vitamin A and D together, in drop dosages and palariable form, thus permitting the physician to prescribe any desired potency of these vitamins and any desired combination

Smaco Cod Liver Oil, fortified with primary vitamin A and natural vitamin D, is available for those physicians who prefer to prescribe cod liver oil This Smaco product has two outstanding advan tages, namely - the cost is approximately one-balf as much as the same vitamin content of plain cod liver oil and only one third the dosage is requited

Smace Products, like S. M. A., are ethically adsertized and carefully distributed through prescripton pharmacter. No design are given to the lasty. Each package carries this statement. We are prescribed by your physician.

investigate in the light of its own peculiar requirements, those plans and suggestions advanced to provide a better service for the indigent sick. In this investigative work we shall continue our own efforts and pledge to the several counties our cor-

dial cooperation.

"We recommend to the Society that it enunciate the principle that the care of the indigent is a community obligation; that the physician should receive a reasonable compensation therefor; and that the charitable work that will always characterize the profession of medicine should be continued to the class of individuals who are endeavoring, under great handicaps, to maintain their independent financial status.

"In such organizations as may employ a fiscal agent for the purposes of assessment and collection of fees, our attention is called to the fact that such individuals frequently are the products of commercial schools and sometimes are primarily interested in the showing of income over expenditures." . . . "We earnestly recommend that this Society voice the principle that under the conditions cited some physician of the group be selected as an immediate advisor of the fiscal agent and be consulted in the matter of assessment and collection of all fees."

"From our studies and those of the Committee on Costs of Medical Care it is evident that the public itself is responsible for a considerable proportion of present costs of illness through the purchase of ill advised and worse than useless remedies and the services of the improperly or wholly uneducated. That self-diagnosis by the individual which leads him to purchase drugs on the basis of extravagant advertising claims of the manufacturer and without competent advice, is a pure economic extravagance which so frequently brings to our attention the tragic result of a disease far progressed which might have been controlled when the individual first sought a cheap relief. We mention this here only to point out that the greatest cost of self-diagnosis, the purchase of useless and sometimes dangerous drugs or the purchase of the services of the uneducated is not the monetary waste for the time that is lost.

"To those essentially rural communities which are unable to secure resident medical service by reason of inadequate income for the practitioner, we commend as an experiment the plan advanced by the State Health Officer of paying such resident physician a reasonable base income as Health Officer. The family physician is ever the first line of defense and offense in all public health

endeavor and such suggestion is made wholly in the interest of conservation of health and of better medical service."

The Committee also made a supplemental report of 16 pages on Contract and Panel Practice, and quotes extensively from the report of a study made by the Milwaukee County Medical Society, which contains valuable statistics and especially descriptions of Sick Benefit associations of Milwaukee.

DISTRICT MEETINGS IN IOWA

The December issue of the Journal of the Iowa State Medical Society praises a county society "meeting of worth," as follows:

"It is the plan of the Speakers Bureau to publish from time to time the report of the outstanding medical society meeting of that month. Many points may be taken into consideration in judging 'the meeting of merit of the month'—originality of program, type of program, percentage of members present, and other features which tend to build up an active medical society and contribute to the development of the medical profession. Secretaries are urged to send in reports of their medical meetings and include these little details which may win distinction for one of their meetings.

"The 'meeting of merit' for November was the meeting of the second district of the Iowa State Medical Society at Mason City on November 15. The distinctive feature of this meeting was the use of local men for the program. Three of the four speakers were local doctors of the district and the other speaker was from the State University. This plan is in definite contrast to the growing practice of using outside talent, often from outside the state, for any medical meetings larger than a single county medical society meeting. Many counties, even, use men from outside their locality on all or most of their programs, thinking it enhances the interest. The enthusiasm manifested in the program of the second district meeting refutes this idea. This plan of a local talent program is making a real contribution to medical progress in Iowa; it is developing medical leaders in our own state, from among our own members.'

Commenting on the District Meetings, the Journal says:

"These meetings are heading in the right direction Not only are good, practical scientific programs given, but incorporated in them we find much information given that comes directly from the main office, giving the members an up-to-date insight into the general management and policies of the State Medical Society. This is significant. It more clearly sets forth our ideals and keeps afresh any changes that take place or are anticipated in the state organization.

"Nearly all papers or clinical reports are given by local members of the district in which the meeting is held.

"The programs are of a practical nature and the discussions are timely and high class in every way. And why should they not be? We have in each district many good men who are capable of constructive work. How can they be developed? The district meeting is the answer. These men belong to it. They are able and should be responsible for the meetings. Many young men are entering the practice of medicine. The district meeting is the forum in which they may develop and thus help to cement a true loyalty among all the members of our Medical Society throughout the State."

BUREAU OF CORRELATED ACTIVI-TIES IN WISCONSIN

The State Medical Society of Wisconsin has a custom that the President-Elect, as well as the other officers, shall make a report to the House of Delegates. President-Elect Jackson reported to the House of Delegates on September 13 as follows:

"Many of our problems and perplexities are associated with the activities society resorts to in its humanitarian efforts to relieve physical suffering. There is at times on the part of society and its agents a fundamental lack of understanding of the motives which actuate us in our attitude towards some of these activities. Doubtless, at times, our profession also fails to sympathetically comprehend the problems and motives of some of the agencies engaged in public preventive medicine and other fields.

"I should like to see established in this state a far closer liaison than exists at present between the private practitioner of medicine and all other organizations, public or philanthropic, which have to do with any phase of health.

"There already exist in this state all the physical requirements and personnel essential to care

for the health problems of the population in a satisfactory way. To insure harmonious co-operation there should be an annual meeting of minds of those interested in the various phases—a voluntary Bureau of Correlated Health Activitiescomposed of the permanent secretaries, the active and past presidents, and the councilors of all the existing present agencies, a forum at which many perplexing questions could be presented and in telligently solved to the mutual advantage of society and organized medicine. Unless organized medicine occupies a central position and serves as a socially sympathetic guiding influence in moulding the pattern of things medical, the medical profession of this state will inevitably be come steadily more subserviant to lay supervision under political domination.

"To put into effect this suggestion will place an additional burden upon the shoulders of ou Secretary. Based upon my personal observation during the past year, I should like to pay a sincer tribute to his work and personality. If I had been asked two years ago what I thought of him, would probably have replied, 'Oh, George is good fellow,' and let it go at that, thus betraying my own delinquency in failing to keep in touch with the many problems which are always on him.

desk pressing for solution.

"Today, I say he is an exceptionally capabl man in the right place. I feel that our Societ is singularly fortunate in having a man of hi training and ability constantly occupying the ke

position in our organization.

"The majority of us are too busy as practition ers to note in the ever-changing current of passin events those things which concern us as physician until they are accomplished facts. I believe that in the future there will arise many situation where foreknowledge on our part of propose activities by others will provide opportunity for tratual consideration and compromise adjustment and that a Bureau of Correlated Health Activitie with George Crownhart as one of our liaison of ficers is worth our consideration and effort."

This suggestion was adopted by the House o

Delegates.

POST-GRADUATE MEETING IN TEXAS

The Texas State Journal of Medicine for December has the following description of a graduate course in Texas:

"The Fifth District Medical Society will promote for the benefit of the medical profession of Texas, a three-day post-graduate medical meeting, to be held in San Antonio, January 10, 11, 12, 1933.

"The program will consist of morning and afternoon general meetings, with an extended noonhour round-table discussion, immediately following lunch. There will be two night sessions, one of them open to the general public, the latter to be addressed by Dr. E. H. Cary of Dallas, President of the American Medical Association. There will be no discussions of lectures delivered at the morning and afternoon meetings, and none at the round-table discussions except as directed by those leading in the discussion. In other words, if we get the idea, it is intended that a post-graduate course more or less progressive in nature, will be directed by those in charge, with no disconcerting intervention, not even entertainment. The

round-table meetings will be group meetings, and will take the place of the usual scientific sections. One group each day will be devoted to lectures in Spanish. Several of the distinguished guests for this occasion will be from Mexico, which gives the occasion an international air. Many of the addresses in Spanish will be abstracted in English, and vice versa, both at the round-table discussions and in the general meetings.

"There will be seventeen teachers and lecturers in all, many of them well known to the medical profession of Texas, among the latter of whom we might mention Dr. Rudolph Matas of New Orleans; Dr. Francisco de P. Miranda, Mexico City; Dr. W. F. Braasch, Mayo Clinic; Dr. Eugene Dyer of Washington, and Dr. Ernest Sachs of St. Louis.

"The program, on the whole, is very similar to that af the original International Post-Graduate Assembly. There will be no special entertainment features, and no commercial exhibits. The Woman's Auxiliary will see that visiting women are taken care of."

PHENYLAZO-ALPHA-ALPHA-OIAMINO-PYRIOINE MONO-HYDROCHLORIDE (MFD. BY THE PYRIOIUM CORP.)

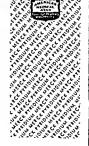

FOR THE TREATMENT

OF GENITO-URINARY INFECTIONS

Combatting genito-urinary infection of venereal or non-venereal origin is a problem many physicians encounter almost daily. In the treatment of gonorrhea, prostatitis, pyelitis, pyelitis of pregnancy, pyelitis in children, vaginitis, cervicitis, and cystitis—where urinary antisepsis is important—physicians are showing a marked preference for Pyridium because of its chemical stability, penetrating action, and antibacterial properties foilowing oral administration. Your focal druggist can supply Pyridium in four convenient forms: powder; 0. 1 gm. tablets in tubes of 12 and bottles of 50 for oral administration; solution for irrigations; and as ointment for topical applications.

DIGITALIS IN HEART FAILURE

In Maine M.J., Sept. 1931, Dr. Paul D. White of Boston asserts that life ean certainly be prolonged and made more useful and happy by restoring and maintaining with digitalis the tone of the heart musele which has begun to fail, whether or not the heart rhythm is normal. It is a wonderful drug, and even without rest, may restore normal heart function. Of course it must be given in the proper dosage.

"The administration of digitalis is still the most important measure of all in the treatment of moderate and marked degrees of congestive heart failure. It can be given rapidly by mouth or intravenously or intramuscularly. If there is not extreme urgency, a satisfactory plan for rapid digitalization is to give two pills or tablets, of 1½ grains of digitalis leaf each, three times a day for two or three days, or three such tablets three times a day for one and one-half to two days (that is, for five or six doses).

Sometimes proper rest and digitalis are not sufficiently effective to dispel congestive failure and edema. It is then that one should turn to diuretics. The salts, like ammonium and calcium chloride, are hardly worth using, except infrequently as adjuvants to more potent diuretics. The purine diuretics, theobromine and its allies, are often effective. The most satisfactory member of this series I have found to be theobromine-calcium salicylate or Theocalcin, given in the dosage of 15 grains

(two 7½ grain tablets) two or three times a day for a few days at a time or longer."

Literature and samples of Theocalein may be had upon request to BIL-HUBER-KNOLL CORP., 154 Ogden Ave., Jersey City, N. J. See page xii.—Adv.

WHAT IS MALTCAO?

THE TREATMENT OF RHEUMATIC FEVER*

By W. W. HERRICK, M.D., NEW YORK, N. Y.

THE treatment of any disease of which the cause is not definitely known must be along empirical lines. Although often unsatisfactory, such treatment may be important and with real influence upon the disease. It is from this viewpoint we may profitably discuss the treatment of rheumatic fever. Measures at our command are local, general and specific. Rheumatic fever is an acute, usually self-limited but very painful disease. A primary object is the com-fort of the patient. This can be furthered by intelligent nursing care. Owing to the profuse sweating, patients are more comfortable between light woolen blankets and clad in cotton flannel. The joints should be immobilized in a comfortable position by pillows, by wrapping in layers of cotton batting, or by well fitting padded splints of wood or light plaster. The local application of methyl salicylate, magnesium sulphate and other substances in solution is probably without value.

The general treatment includes a diet which need not be strict. A simple diet of soft materials in the early stages, gradually increased during convalescence is in order. It should contain ample calories to prevent excessive loss of weight. To replace the fluid lost by excessive sweating and by the use of coal tar products, fluids must be freely given. Because of the large amount of waste material which escapes through the pores of the skin, the patient should be sponged frequently. This must be done without undue manipulation. The drugs which are useful in the management of rheumatic fever are the narcotics, the analgesies and the antipyreties.

In the acute stages, the patient is entitled to an amount of narcotics sufficient to control pain. For this codein or even morphine need not be spared. Nights with good rest thus secured in the early stages of the disease do much to relieve the painful muscular spasm which probably contributes to the discomfort of the arthritis. While the salicylates are of undoubted value, the best evidence available indicates that the disease is not shortened or its complications lessened in number or severity by the use of this drug.

'Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

However, under these products of coal tar, the discomforts of the disease are greatly mitigated; pain is lessened, fever is diminished and the general comfort and well-being of the patient are furthered. The margin between the therapentic and toxic doses of the salicylates is narrow. To attain a satisfactory therapeutic effect, it is therefore necessary to approximate the toxic effect. The average toxic dose of sodium salicylate for adults is about ten to twelve grams (grains 150 to 180) in twenty-four hours; of aspirin, ten grams (grains 150); of methyl salicylate or oil of wintergreen, eight cc. An accepted method is the administration of one to two grains of sodium salicylate or one to one and one-half grams of aspirin every hour for eight to ten doses or until toxic symptoms appear. These symptoms are those of einchonism; tinnitus, nausea, voiniting, loss of appetite, delirium; or those of shock; eyanosis, dyspnoea, low blood pressure. pallor, faintness, even collapse; or those of hypersensitiveness; largely dermatoses. At any hint of these evidences of toxic action, the drug should be stopped for from twelve to twentyfour hours and then one-half the former dosage resumed, gradually lessening until the manifestations of the disease are no longer present. Such gradual withdrawal seems wiser than sudden withdrawal and is thought to result in less frequent relapses. In the event of marked gastric disturbance following the oral administration of the salicylates, the drug may be given in solution by rectum in doses about 50 per cent greater than those suggested for oral use. Auother compound of salicylate acid used in treating this disease is pyramidon. In average doses of from two to four grams per day, this does not cause the toxic symptoms so often seen with sodium salicylate and is to be recommended when these are feared.

The cinchoninic acid compounds, atophan, tolysin, neo-cincophen, act very much as do the salicylates. Their use, however, is probably unwise because of the occasional toxic influence upon the liver. Numerous examples of icterus followed by necrosis of the liver, some with fatality, are on record following the use of even small amounts. In addition to this danger these compounds are expensive. It is probable that their use should be abandoned.

The use of such non-specific protein substances as typhoid bacilli, cascin, or scrums of miscellancous origin is often followed by benefit. Their subcutancous, intravenous, or intramuscular injection may lead to a reaction marked by chill, fever, lecuocytosis, to be followed by a subsidence of the fever, and of the manifestations of arthritis which may be temporary or more enduring. In some cases this improvement is dramatic, striking and almost convincing. At the present time, however, those most experienced are hesitant to advise and employ this somewhat drastic measure in a disease which has such serious visceral complications. While a conservative attitude does not necessarily condemn this form of treatment, its routine use cannot be advised unreservedly.

Until the cause of rheumatic fever has been definitely established, it may seem futile to discuss specific therapy. However, so many of the manifestations of acute rheumatic fever resemble those of hypersenitiveness to streptococci, that the use of streptococcic anti-serum or of streptococcic vaccines is suggested. The results of such attempted specific therapy are still a matter of experimentation and debate. With our present knowledge treatment with streptococcic anti-serum seems to fall into the same category as that of non-specific therapy and need not be separately discussed.

Recently much experimental work has been done upon the intravenous vaccination of patients with strains of streptococci isolated from the throats of patients with or convalescent from acute rheumatic fever. Apparently this method is a two-edged sword. In the acute stages of rheumatic fever, patients are very sensitive to such vaccines and their administration may be followed by an exacerbation of the disease. When the patient is at a stationary or sub-acute stage of the disease, the judicious administration of this vaccine may give an added impetus toward recovery, and it is possible that relapses may be prevented by such vaccination. There is experimental evidence pointing toward a state of hypersensitiveness to the streptococcus as a result of vaccination, a state followed by one of

hyposensitiveness which is again replaced by a hypersensitiveness. A therapeutic measure thus complicated and with the possibility of harm is one not to be undertaken at random and one the value of which is sub judice.

A point of great importance in the management of acute rheumatic fever is the elimination of foci of infection. It is apparent that infected tonsils, infected teeth, infected sinuses and possibly similar foci elsewhere in the body contribute to the prolongation or recurrence of an attack of this disease. The removal of such foci during the acute attack is often attended with For example, after tonsillectomy the danger. blood culture may become positive and the entire clinical picture change for the worse. general it seems best to wait until the acute manifestations of the disease have subsided before making a surgical attack upon local infectious. However, in the prolonged and recurrent cases a different attitude may be taken with advantage.

Of paramount importance in the management of this disease is the proper care of certain of its complications. Pericarditis and pleurisy with effusion are best treated by rest and aspiration as indicated. Most important of all are the cardiac complications. For these prolonged avoidance of bodily activity is essential. A good clinical rule is to enforce complete rest until all evidences of cardiac enlargement have disappeared and until the pulse rate and the response of the heart to exercise are normal. For this even one or two years may be needed. Following any other course exposes the patient to the risk of chronic invalidism. In the management of long continued cases or of cases with tendency to relapse methods found helpful in the treatment of other chronic infections such as tuberculosis offer much. Sunshine, fresh air, liberal diet with excess of vitamins are most helpful. Advantage may be taken of the observation that rheumatic fever is almost unknown in tropical and subtropical climates. In the persistent or recurrent case, a prolonged stay in Florida, the American southwest, Bermuda, Cuba or Porto Rico may be undertaken with profit.

Note: For a complete discussion of Rheumatic Fever with references to recent literature the reader is referred to the monograph of Homer F. Swift in the Nelson Loose-Leaf Medicine.

THE CARE OF COMA FROM UNKNOWN CAUSE*

By E. D. FRIEDMAN, M.D., NEW YORK, N. Y.

THE physician frequently encounters patients in coma or stupor. The determination of the causes of the varying degrees of unconsciousness is the important factor since treatment is

dependent on it. I shall therefore discuss our problem according to the dictum laid down many years ago by the famous clinician Gerhardt: first examine, then diagnosticate, and finally, treat.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

The history is extremely important in every case, especially as to (1) the incidence of previous

iliness (otitis, sinus disease, diribetes, nephritis);
(2) the presence of injury, (3) the mode of onset (sudden in apoplexy and subarachnoid bleeding, gradinal in subdirial hematoma, uremia, diabetes), and (4) the associated symptoms, such as convulsious, headriche, dizziness and vomiting

In all cases the head should be examined for cyidences of local injury or bleeding from the various orifices. The examiner should be on the lookout for the odor of alcohol in the breath and the blood pressure should be determined (high in urenua and advancing compression of the brain) The urme, which should be obtained by catheteriation, must be examined for the presence of sugar, acctone, albumin and casts. In this connec tion it is important to remember that sugar may appear in the urine after epileptic and apoplectic seizures. In such instances the glycosuria rarely persists for more than twenty-four hours, it has been ascribed to disturbances in the Claude Bernard center in the fourth ventricle The blood must also be examined for evidence of nitrogen retention and hyperglycenna

In many of the cases we find conjugate deviation of the eyes—in cases of profound apoples, the patient "looks at his lesion". Foerster and others have described a number of oculogyric centers in the brain, frontal, parietal and temporal in location. When these centers are irritated they cause cephilo and oculogyric movements to the opposite side, when they are paralyzed, the head and eyes are turned toward the side of the de-

structive lesion The facies must be examined for evidence of asymmetry, the evegrounds looked at (after mydriasis) for signs of albuminurie or diabetic retinitis and choked disc. The superficial and deep refleves must be carefully gone over. In profound coma all the reflexes are abolished but in most cases of apoplexy the superficial reflexes are diminished on the side of the hemiplegia. I have found that the unilateral abolition of the corneal reflex is an important sign of coma due to vascular lesions of the brain 1 It is frequently associated with loss of the abdominal reflexes and diminution of the plantar response on the same side deep reflexes are usually diminished or absent in all cases of increased intracranial pressure and, currously enough, this is more often the ease with the knee jerk than with the Achilles reflex. The deep reflexes may also be diminished as a result of diabetic "pseudo tabes". The presence of a The presence of a positive Babinski sign is of great significance. In the early stages of apoplexy and in subarachnoid hemorrhage this sign is usually present bilaterally

The state of muscle tone must also be determined In coma there is, as a rule, general flacedity of the limbs except in cases of intraventricular bleeding in which we find generalized rigidity Lumbar punetures must also be carried out. It is extremely important for the detection of the various forms of meningitis and subaraclinoid bleeding. In some of the cases of skull injury the intrathecal pressure is very low. In my experience this is a bad prognostic sign. A ray examination of the skull injust also be performed in order to determine the presence of fracture of the skull or convolutional markings due to increased intracramial pressure.

Causes of Coma

- I General (such as alcoholism, urema, dia betes, optum and gas poisoning, and hypoglycenne states)
- II Lpilepsy
- III Intracramal lesions with or without focal signs
 - (a) Apoplexy
 - (b) Meningitis
 - (c) Abseess of the brain (d) Tumor of the brain
 - (a) Tumor of the brain
 - (f) Spontaneous subarachnoid hemoirhage

IV Trauma

- (a) Concussion of the brain
- (b) Gross hemorrhige with or without fracture

1 General Causes

Alcoholic come is recognized by the odor of alcohol in the breath, the incidence of vomiting dehrum and restlessness

In the tremic cases we find evidence of nephritis, characteristic changes in the finidility pertension, edema of the limbs, high introgen figures in the blood and transitory homplegias or monoplegias. The onset of coma in these cases is usually gradual and is preceded by headache, vomiting and other evidences of infoxication.

Opum poisoning can be identified by the small pupils the relatively good pulse and the shallow breathing. In cases of gas poisoning there is a lustory of exposure, at times, one may detect a characteristic odor in the breath, and the spectroscopic test is positive. The patient usually presents marked cyanosis with a peculiar redness of the skin.

In diabetic coma we find the "soft eyeball' (due to low infraocular tension), elevation of the blood sugar level and signs of acidosis, including low CO, combining power in the blood. There is frequently a listory of preceding nausea, vomiting and epigastric pain. Physical examination reveals the characteristic Kussmaul breathing, low temperature, and dryness of the skin (due to dessication of the tissues).

Hypoglycenic shock is usually the result of liverinsulmism. I recall two instances of this

¹ Unilateral Anestlesia of the Critica and Conjunctiva A Diagnostic Sign of Comp Due to Hemplegia E D Treelman M fl Journal of the A M A June 21 1919 Vol 72 p 1812

type of stupor. One was a case of suprasellar cyst with hypoglycemic crises, the other proved to be a tumor of the third ventricle. The hypoglycemic states were temporarily relieved by the intravenous administration of glucose.

II. Epilepsy.

Post-epileptic stupor is identified by the history, evidence of tongue bite, and the usually rapid recovery.

III. Intracranial Lesions.

- (a) Apoplexy. Apoplexy is one of the most common causes of coma and is due to either hemorrhage or thrombosis. The latter is more apt to occur slowly, especially during sleep, while the onset of hemorrhage is usually sudden. the typical case the face of the patient is flushed and cyanotic, the breathing is stertorous, the blood pressure is elevated, the pulse is slow and full, and there is general flaccidity of the limbs, more pronounced on the paralyzed side. As a rule, we find conjugate deviation of the eyes and head, either away from the lesion in cases of irritation of the oculogyric centers, or towards the lesion owing to paralysis of the oculogyric mechanism on the affected side. The pupils are dilated and fixed unless the hemorrhage is pontine in localization. The deep reflexes are at first diminished but the Babinski sign is positive. The corneal reflex is lost on the hemiplegic side (v.s.). The temperature rises and in the fatal cases the scene ends with a terminal hypostatic pneumonia. these individuals one usually obtains a history of nephritis and hypertension and, frequently, a history of preliminary small "insults" with dizziness and defects in memory, antedating the major attack.
- (b) Meningitis. Meningitis may be a cause of coma or stupor. It may be primary (tuberculous. meningococcic, or influenzal in type), or secondary, following or accompanying otitis and sinusitis.

In the tuberculous type, one may frequently elicit a history of bone or joint tuberculosis or there may be evidence of the primary infection in the lungs or kidneys. It may follow in the wake of Pott's disease of the spine. It may be accompanied by miliary tuberculosis in the lungs. The lesion in the brain is, as a rule, most marked in the interpeduncular space, hence the frequency of oculomotor palsies. At first the meningeal signs are only suggestive but later on one can demonstrate distinct rigidity of the neck and the positive Kernig sign. The spinal fluid is characteristic: it is fairly clear and colorless but may be xanthochromic. There is a definite lymphocytosis which rises as the disease process advances; the protein is increased and the sugar content falls progressively; after a few hours, a pellicle forms in which the tubercle bacilli can frequently be demonstrated.

The meningococcus infections are as a rule

more fulminating, there is more constitutional disturbance and the meningitic phenomena are more pronounced. Herpes is frequently present. The spinal fluid is purulent and usually the gram negative meningococci can be found in it; its sugar is reduced in amount or entirely absent.

The secondary meningitides usually accompany otitic or sinusitic disease and may be either abacterial (sympathetic) or bacterial in nature. In the sympathetic forms one finds either a polynticleosis or lymphocytosis in the spinal fluid but no organisms in the smear or culture; the sugar content is not seriously altered, and the meningeal signs are not pronounced. I have seen relief in such instances from the eradication of mastoid disease, or the clearing out of infective matter from the involved sinus. The secondary bacterial meningitides prove almost uniformly fatal.

(c) Abscess of the Brain. Brain abscess is another cause of stupor or coma. It may be otogenic, in which case it involves either the temporal lobe or the cerebellum. It may also accompany sinus disease, especially disease of the frontals and sphenoids. I have seen one case of temporal lobe abscess as a sequel of an intranasal operation for a sinus affection. Brain abscess may be metastatic in origin, secondary to a primary focus in the lung; in such instances it is usually a terminal event. It is important to remember that brain abscess may also be found as part of the picture of general sepsis.

As a rule, the patient is mentally torpid, the pulse is slow, and the temperature is only slightly elevated. In most instances there are focal signs pointing either to the temporal lobe (speech and field defects) or to the cerebellum (mystagmus and cerebellar phenomena).

- (d) Tumor of the Brain. Occasionally, hemorrhage into a tumor (a latent glioma, especially of the right hemisphere) may be ushered in by an attack of stuporousness. In such instances the presence of focal signs and changes in the fundi lielps to identify the lesion.
- (e) Encephalitis. Encephalitis as a cause of coma may be a primary process, when it occurs in epidemic form, or as part of the syndrome of Heine Medin's disease (poliomyelitis). It may be secondary, when it follows in the wake of measles, vaccination, varicella, or other infectious dis-

It may also be the result of salvarsan intoxication. In such instances it is hemorrhagic in type and usually fatal. There is nothing in cases of this group to suggest either a vascular accident or an otitic complication and the spinal fluid is usually normal.

There is another type of encephalitis described by Wernicke as polio-encephalitis superior alcoholica. It occurs in chronic alcoholics. lesions are largely peri-aqueductal in location, as in epidemic encephalitis, hence the frequency of nystagmus, ocular muscle palsies, somnolence, and bladder retention. The spinal fluid may be nanthochromic. I have seen one individual who presented this syndrome in association with widespread alcoholic polyneuritis and a typical Korsakoff psychosis.

(1) Spontaneous Subarachnoid Hemorrhage. Spontaneous subarachnoid hemorrhage is a frequent cause of coma. It may occur at all ages. Its onset is usually abrupt, with pain at the nape of the neck, headache, and voniting. Stupor rapidly supervenes. Very soon thereafter, the patient exhibits fever, leucocytosis, and slowing in the julse. Physical examination reveals the signs of meningitis and lumbar puncture reveals a characteristic spinal fluid. It is uniformly bloody but does not coagulate; if the test tube is allowed to stand, the supernatant fluid is usually xanthochromic. Later on, there may be a reactive lymphocytosis in the spinal fluid (foreign body reaction).

The most frequent cause of spontaneous subarachnoid bleeding is rupture of a miliary aneurysm at the base of the brain involving one of the branches of the circle of Willis. There may be a history of diplopia and trigeminal pain and occasionally nne may demonstrate evidence of a third nerve lesion (ptosis, dilatation of the

pupil).

These aneurysms may be congenital, in which case the patient may exhibit the external evidences of the so-called thymolymphatic constitution (horizontal pubic hair, scant heard and body hair in the male, hypoplastic cardiovascular system). They may also be encountered in adults with hypertensive disease and in children suffering from subacute infectious endocarditis, who develop mycotic aneurysms in the cerebral vessels. Many of the patients recover and give a history of a number of episodes of meningeal irritation. Some of the cases, however, prove rapidly fatal. The prognosis depends entirely on the size of the rent in the vessel.

I have seen a number of cases of subarachuoid bemorrhage which presented, in addition to the meningeal symptoms, signs of a hemisphere lesion and papilloedema. These gradually disappeared. Such cases are important because they may simulate cerebral neoplasm. In these instances aerographic studies may become necessary for final differential diagnosis.

IV. Trauma.

Trauma may give rise to either concussion of

the brain or gross hemorrhage.

Concussion differs only quantitatively from contusion of the brain. In these cases there are local signs of injury and the stupor follows the trauma immediately. Concussion was at one time ascribed to an acute compression of the brain with cerebral anemia; we now believe that it is

due to minute perivascular hemorrhages in the cortex, basal gauglia and midbrain. The blood pressure in these cases is usually low.

Gross hemorrhage may be either epidural (from laceration of the middle meningeal artery), subdural, subaraclmoid or intracerebral.

- (a) Epidural hemorrhage follows soon after trauma. In most instances there is a brief free interval but this is not always the case. At first there are signs of cerebral irritation, later increasing stupor. The diagnosis of the lesion is extremely difficult and many of the cases are overlooked only to be discovered at the post norten examination. X-ray examination of the skull may be of assistance, especially if the fracture involves the temporal bone. In such cases the diagnosis of laceration of the middle meningeal artery can be entertained.
- (b) Subdural hemorrhage occurs outside the subarachnoid space; it varies only in degree from the condition described as pachymeningitis hemorrhagica interna. It may be encountered in cases of general paresis and chronic alcoholism. It is especially apt to occur in the wake of a relatively slight trauma. The bleeding is ascribed to rupture of the veins which enter the longitudinal sinus almost at a right angle; the oozing continues until a fairly large clot forms on the surface of the brain. These subdural clots are usually extensive in the antero-posterior diameter of the skull and are frequently bilateral.

There is, as a rule, a considerable free interval after the injury (thus differing from middle meningeal bleeding). Often the patient has completely forgotten the tranna. He may resume his work, although he appears to be retarded and not quite himself. Later, he develops headache, dizziness, vomiting and signs of increased intraeranial pressure (slow pulse and choked disc). At first there is drowsiness which later deepens to coma. Periodically, the patient emerges from and relapses into stupor. Lumbar puncture usually reveals no abnormalities aside from increased intrathecal pressure (the subdural sac being distinct from the subarachnoid space). At times, however, the fluid may be xanthochromic.

In most cases of subdural hematoma there are focal sigus pointing to a lesion in one hemisphere, and in a number of instances homolateral dilatation of the pupil has been found. In many of our cases the hematoma was looked for over the apparently involved hemisphere but it was not found there. Exploration of the other side was then carried out and the hematoma located. This anomalous situation has been ascribed to a contre coup mechanism, the hematoma on one side displacing the entire brain to the opposite side or jamming the brain stem against the tentural incisure of the opposite side, thus giving rise to ipsolateral pyramidal tract signs.

(c) Subarachnoid bleeding may accompany

fracture of the skull but it is frequently non-

traumatic in origin.

(d) Trauma may also give rise to intracerebral bleeding without fracture of the skull or subarachnoid hemorrhage. I have observed at least three instances of this syndrome following trauma. They all presented signs of a focal lesion in the brain. Exploration failed to reveal the presence of either epi- or subdural bleeding but aspiration of the brain yielded bloody fluid. Two of the cases terminated fatally, the third is still alive but presents clinical evidence of a residual lesion in the right hemisphere. These cases deserve further study.

Intraventricular hemorrhage usually accompanies the apoplexies in which the bleeding plows its way through the brain substance and reaches the ventricle. Patients with this condition exhibit convulsions, generalized muscular rigidity, meningeal signs, bradycardia and bloody spinal fluid.

These cases prove rapidly fatal.

TREATMENT

General Considerations in the Treatment of Skull Injury and Increased Intracranial Pressure²

It is our practice not to employ morphine. It often has an irritating effect on the patient, raises intracranial pressure, and masks the symptoms.

Lumbar puncture is carried out both as a diagnostic and a therapeutic measure. Hypertonic dextrose solution is employed for the purpose of dehydrating the brain. We usually administer 100 cc. of 50% dextrose solution intravenously three times a day. This is given directly from the ampule, if possible, in order to forestall chills. Caffeine sodium benzoate is administered by hypodermic injection in doses of 7½ grains (0.5 gm.) every four hours. By means of rectal instillation or a rectal drip, 100 cc. of 25% dextrose solution is given every four hours.

The head of the bed is elevated from 30 to 60 degrees. In cases of suspected epidemic meningitis, anti-meningococcus serum is administered. Ventricular puncture is carried out only if these measures prove inadequate.

Operative procedures are necessary in compound fractures of the skull and in cases in which the presence of middle meningeal hemorrhage or subdural bleeding is suspected. In both of the latter conditions a bilateral trephine exploration is carried out for reasons already mentioned. Uncomplicated depressed fractures of the vault may be elevated after the stage of acute shock has passed. Surgical interference in all such individuals may be safely postponed for a time. Right sub-temporal decompression is resorted to only in comatose patients who exhibit papilloedema and who do not respond to the regime out-

lined. The treatment of simple fracture of the skull is expectant.

Treatment of Other Conditions

In cases of morphine poisoning the Drinker apparatus is made use of in order to assist the embarrassed respiration. In the cases of alcohol and morphine poisoning, gastric lavage and supportive therapy are employed.

For cases of gas poisoning a mixture of 95% oxygen and 5% CO₂ is administered by inhalation. Venesection followed by transfusion of normal blood or the intravenous administration of physiological saline solution is also helpful.

In the cases of subarachnoid bleeding, lumbar puncture is carried out at first for diagnostic and later for therapeutic reasons (if there are signs of increased intracranial pressure). It should not be performed too frequently, however, in order to permit local clotting at the site of aneurysmal rupture and to forestall further bleeding.

For primary meningococcus meningitis, lumbar puncture is performed daily; serum is administered both intravenously and intraspinously until the constitutional symptoms disappear and the cerebrospinal fluid clears up. For the secondary meningitides, especially the sympathetic forms, mastoidectomy, surgical removal of foci of petrositis and evacuation of purulent material from the sinuses should be carried out. The secondary bacterial meningitides usually prove fatal although I have seen recoveries in isolated cases of pneumococcus, staphylococcus and influenzal meningitis following repeated lumbar puncture.

In cases of brain abscess it is advisable to make a trephine exploration over the suspected zone and evacuate the pus. This, however, should not be done until a period of four to six weeks has elapsed in order to permit capsule formation and thorough localization.

In the cases of apoplexy the patient is placed in a lateral prone position, with the tongue held forward. Bromides and chloral are administered for restlessness. In the plethoric, hypertensive cases, venesection with removal of 250-500 cc. of blood is carried out; the patient's posture should be changed at intervals to forestall hypostatic congestion of the lungs. The best treatment in the early phase of this condition is judicious negligence.

In cases of uremia venesection is practiced (up to 500 cc. of blood being withdrawn). This is followed by the injection of physiological salt solution to dilute the toxins. We also make use of intravenous injections of magnesium sulphate and dextrose solutions. In cases with pronounced disc changes suggestive of increased intracranial pressure, lumbar puncture is performed.

² "Modern Treatment of Increased Intracranial Pressure," F. Kennedy, M.D., and S. B. Wortis. M.D., The Journal of the A. M. A., Apr. 18, 1931, Vol. 96, p. 1284.

Cases of diabetic coma are put to bed; local heat is applied; insulin injections are given in the proportion of one unit for each two grams of sugar in the urine; and large quantities of fluid along with orange juice are administered. Sodium chloride and bicarbonate of soda solutions

are also given by rectum and by vein to combat the dehydration and the acidosis.

The treatment of hyperinsulinism and hypoglycemic crises in general consists of the intravenous administration of glucose.

The treatment of brain tumor is surgical.

TREATMENT OF THE COMMON LEUCORRHEAS* By JAMES E. KING, M.D., BUFFALO, N. Y.

If the general practitioner should aequaint himself with the causes and treatment of backache and leucorrhea the gynecologist would be deprived of a large part of his office practice. A half hour's thoughtful consideration of the common leucorrheas would clear up all misconceptions as to their cause and treatment. I shall attempt to give the basic principles in twelve minutes.

There are only three possible sources of the common lencorrheas: the endometrium, cervix, and vagina. The endometrium was formerly believed a frequent source. It is now known that the endometrium rarely produces discharge except in acute specific or non-specific infections. For the purposes of this discussion, therefore, discharge from the endometrium may be ignored.

There remain for consideration two sources of lencorrheal discharge, the cervix and vagina. Inasunuch as the type of discharge from each has well-defined characteristics, they should be distinguished as cervical leucorrlica and vaginal lencorrhea. In those instances in which both types co-exist the term cervico-vaginal leucorrhea is suggested. It must ever be borne in mind, however, that leucorrhea is but the clinical expression of an underlying pathology and it is only by understanding that pathology that the physician may hope to appreciate the true significance of leucorrhea and to adopt rational procedures in treatment.

The size of the cervix and length of its canal vary in different women. The canal is lined by a membrane which is generously provided with deeply branching racemons glands whose secretion consists of a thick, tenacions, glary mucons. A normal secretion provides a mucous plug for the cervix. Hypersecretion is evidenced by an increased elaboration of this same characteristic mucous and which when present at once declares its source.

Etiologically there are two general headings under which the cervical lencorrheas may be classified: those which are not the result of infection and those which are the result of infection. The non-infected group is not uncommon. It is encountered in virgins, the nulliparons and the parons. In this group the cause of such

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. V., May 25, 1912.

hypersecretion is not always clear. It is frequently present in tall, stoop-shouldered, constipated, acne-marked, ill-nourished 'shop girls—a fact which suggests, in some instances at least, a constitutional cause.

The cervical leueorrheas due to infection constitute by far the larger and more important They naturally divide themselves into those caused by a non-specific infection and those due to so-called specific or gonorrheal infection. In the non-specific infections the less virulent strains of the staphylococcus and streptococcus are the chief offenders. Such infections most commonly follow abortion and labor. At that time there may have been no clinical manifestations suggesting infection but later a yellowish tenacious discharge indicates the presence of Frequently associated with an endocervicitis. the endocervicitis are varying degrees of cervieitis evidenced by enlargement, erosions and cervical eysts. Chronic gonorrheal endocervicitis may clinically be indistinguishable from the non-They both have the yellowish specific group. tenacious mucous draining from the os. History and bacteriological study only will differentiate

The treatment of endocervicitis and its attendant cervical leurorrhea is clear cut and rational. The misconceptions prevailing in the past resulted in a misdirected therapy. Curetage, douches, and medicinal treatment of the cervical canal cannot be and are not curative. The real cause of the mucous discharge lies in the hypertrophy and consequent hypersecretion of the glands. The remedy, therefore, consists in removing or destroying, in whole or in part, these glands.

The treatment of cervical lencorrheas in virgins often presents a difficult problem. It is important here to give the general condition of the patient due consideration. Unfortunately those measures best calculated to improve the patient's constitutional state 'are often economically beyond her reach. In those whose cervix is accessible general measures may be supplemented by modified gland destruction.

After the true significance of cervical lencorrhea became understood and the necessity for removing the glands became clear, amputation of the cervix was frequently resorted to. This is a mutilating operation that today seldom finds place. Removing the glands by coning out the cervix and infolding the cervical shell as proposed by Sturmdorf is an improvement over amputation.

Destruction of the glands by other than surgical means can be accomplished effectively in three ways: the nasal loop cautery, surgical diathermy, and electro-coagulation. The nasal loop cautery requires the least outlay for apparatus and with a little experience its use is highly satisfactory. A number of treatments are required as only a part of the canal is cauterized at a treatment. The loop is introduced cold into the canal as far as the internal os. The loop being heated is slowly withdrawn, pressing its side against the part of the canal chosen for cauterization. Two or three of these lines of cauterization are made at a treatment. Other treatments follow at three or four week intervals until a sufficient number of the glands have been de-The treatment causes but little pain. The beginner should acquire his experience by first using his cautery on cervical lacerations. In this way he becomes familiar with the proper degree of heat to use and how best to gauge the depth of cauterization.

Surgical diathermy is in some respects an improvement over the cautery. It is more positive in action and somewhat better controlled. The applicator consists of a wire an inch and a half in length, one end of which is attached to the end of the electrode and the other to its side so that the wire lies parallel to and raised about 1/8 of an inch above its surface. This applicator introduced into the canal and the current applied will cut its way into the mucous membrane destroying the glands in its path. By the use of a special applicator the entire gland bearing surface of the canal can be quickly and neatly could This may be done as an office procedure under local anæsthesia as advocated by Hyams. In three or four weeks the surface of the canal becomes relined by an ingrowth of squamous epithelium from the surface of the cervix. plan accomplishes more simply the same result as the Sturmdorf operation.

The third method is by electro-coagulation. This is a still more simple procedure. A bipolar applicator designed for the purpose is inserted into the canal, the current applied, and the applicator rotated. The amount of current and length of application will determine the depth of coagulation. In a few days the slough separates and the surface is left clean for epithelization.

Douches in cervical leucorrheas, while in no sense curative, do contribute to the patient's comfort. An alkaline douche aids in clearing the vagina of collected mucous.

The foregoing epitomizes the treatment of

cervical leucorrheas. The method employed will depend upon whether the physician wishes to make an initial outlay of \$50 or equip himself with a more expensive electrical appliance.

Passing now to a consideration of the vaginal leucorrheas it becomes at once apparent that one is dealing with an entirely different underlying pathology based upon a very different histological structure. The vaginal walls and cervix are covered by a squamous epithelium comparable to that of the skin. The vagina, however, differs from the skin in the important particular that it contains no glands. A discharge, therefore, originating in the vagina cannot be the result of glandular hypersecretion but must be due to some condition which produces a serous exudation. A vaginal leucorrhea is therefore in the nature of a serous discharge lacking the thick, tenacious qualities of cervical discharge.

A physician who proposes to treat vaginal leucorrhea should familiarize himself with the appearance of the healthy vagina and the amount and character of secretion normally present. The secretion under normal conditions varies somewhat as to amount and character depending upon when the observation is made. Just prior to or just following menstruation it is often increased. Some women have a small amount of pearly gray fluid constantly in the vaginal vault but not sufficient to cause unpleasantness. Some, too, seem to desquamate the vaginal epithelium more freely than others. In women in whom the abundant

The principles underlying vaginal leucorrhea are not difficult to understand. To discuss in detail the clinical features of the various types would require more time than is at our disposal.

desquamation takes place the vaginal vault may

show collections of epithelial cells in masses

which in color and consistency resemble cottage

cheese. Such is not in strict sense pathologic.

It may be said that infection is a cause or a secondary factor in all chronic vaginal leucorrheas. The vaginal wall, by virtue of its natural defenses, is reasonably resistant to infection but when once seated, an infection tends to become chronic. It is not known under what conditions infections become possible. They are seen in the married, in virgins, and in those less discrect.

Inasmuch as the appearance of the vagina is essentially the same in the various types of vaginitis, one broad, general description will suffice. Based upon appearance it is possible to recognize, first, those cases where the vaginal walls are not the normal pink but a uniform brighter red; second, cases which will show upon careful inspection small punctate bright red areas on the generally reddened surface and third, a reddened granular surface which is but a more advanced stage of the last.

The cause of this reddened appearance is the reaction of the superficial epithelium to infection.

The punctate areas denote a desquamation of the epithelium in spots from which serum exudes. Every vaginal leucorrhea, therefore, has as its background a vaginitis. It is impossible to define sharply the type of infection in all cases, as sooner or later all become mixed infections. While not entirely accurate, vaginitis may be classified etiologically under three headings: vaginitis due to a mixed infection of the more common organisms; vaginitis due to the trichomona; and finally, the so-called senile or atrophie vaginitis. The saphrophytes are almost never the primary cause of vaginitis and play a part only as a secondary infection. They are the camp followers whose presence accounts for the offensive odor often noted in these discharges. In the mixed infection, pure and simple, the discharge is vellowish in color and sero-purulent in character. Without treatment it tends to persist but with a rational therapy it may be promptly cured.

The most important and most common vaginitis is one due to a specific organism, the trichomona. In 1836 this organism was described as a cause of vaginitis and in a few years a number of observers had confirmed the original observations. It is a curious fact that it then became forgotten until a few years ago when it was re-discovered and now it occupies an important place in any discussion of vaginal leucorrhea.

The trichomona is an amoeba-like organism belonging to the group of flagellates. Its source is still in dispute. It does not take the ordinary stains readily and can best be seen under the

microscope in the hanging drop.

Clinically it is associated with certain well-defined features. It may effect almost any age, the child-bearing period being the most common. The parous, nulliparous, and the virgin may all be victims and very frequently it is encountered in pregnancy. It may develop gradually or the onset may be acute. Once established a trichomona vaginitis is marked by well-defined symptoms and by fairly constant physical findings. The chief complaint is a profuse sero-purulent discharge which is accompanied by itching or burning about the vulva. With the presence of saphrophytes the odor may be very offensive. Upon examination the vulva is seen to be reddened. A speculum will disclose, puddled in the vaginal vault, a creamy sero-purulent collection on the surface of which are small bubbles. Even though apparently there may be no saphrophytic infection the discharge very often assumes a peculiarly sickening odor. Cotton readily removes the discharge. The vaginal wall is then seen to be reddened with a certain lack-lustre appearance. Closer inspection will reveal the punctate areas of desquamation upon the cervix and vaginal wall. In well-marked instances the vaginal wall and cervix may resemble a scarletina raslı. The above symptoms and findings are classical and in themselves justify a diagnosis of trichomona vaginitis.

The atrophic or senile vaginitis is the plague of the postmenopausal period of life. atrophy which takes place in the vaginal and cervical epithelium lessens the vitality of the cells. In consequence of this, exfoliation of cells easily occurs leaving small exposed areas unprotected. Such surfaces exude serum and this serum affords a natural culture medium for bacteria which only too soon find their way into the vagina. With infection present and under the influence of the purulent discharge the atrophic squamous cells are macerated and shed leaving other fresh surfaces to exude still more serum. This purulent discharge bathing a vulva whose atrophy affords poor protection, soon produces an intolerable itching and burning which torture these patients by day and by night. While in many instances infection may follow the desquamation of atrophic cells, in other instances an infection may be primary in the atrophic vagina. In either case the result is the same and practically it makes little difference which factor initiates the process.

The treatment of all forms of vaginitis has certain general principles applicable to all. The patient's complaint is of a discharge and vulval itching. The physician rightly assuming infection to be the underlying cause proceeds to institute measures to eliminate it. While he sees clearly the indication he usually errs in his choice of a method. He fails to visualize the irritated vaginal walls and the denuded areas, and prescribes a douche that is irritating. Iodine, lysol, or some donche powder is often his choice. Following their use there is an increase in discharge as such agents by irritation promote further exudate. Any value such agents have as antiseptics is but transitory for by their irritation they increase the serum upon which the infection feeds. What then are the correct indications in the treatment of any vaginitis? Recognizing that the vaginal walls are irritated and the cells macerated by the presence of the infected discharge, which itself is the result of a serous exudate, the first indication is clearly to reduce exudation. The inflammed vaginal walls being in contact favors further maceration and obstructs free The second indication, therefore, would be to keep, in so far as possible, the vaginal walls from contact by the use of some material that will absorb the exudate.

To meet the first indication one would choose a douche that is non-irritating and that possesses astringent and antiseptic properties. Such an agent is found in zinc chloride. The patient is given a solution containing 30 to 45 grams of zinc chloride in 240 cc. of distilled water. To this is added 1 cc. of hydrochloric acid to aid

solution. Of this 8 cc. are used in a quart of water at night just before retiring. In severe cases a morning douche may also be taken.

The second indication is met by the liberal use of a powder in the vagina and the insertion of an elongated absorbent tampon. The powder aids in keeping the vagina dry and the tampon separates the vaginal walls and absorbs any exudate. The tampon remains 12 to 24 hours, its removal being followed by a douche. These treatments may be given every 3 or 4 days. Many powders have been used but the writer prefers one composed of equal parts of calomel, boric acid and bismuth subnitrate. Where itching is a prominent feature an elongated cotton pleget is placed between the labia after a generous application of talcum powder. This keeps the labial surfaces from contact and absorbs any discharge. Such treatment will invariably give relief and in the cases of mixed infection or atrophic vaginitis, will soon cure. In the case of trichomona vaginitis, however, one is dealing with a most persistent infection and the douche must be continued for a long period after the discharge has apparently completely disappeared. Neglect to do this is the most common cause of failure to Many other methods have been tried in the search for some means that will promptly and completely eliminate the organism. Among the methods in favor are scrubbing the vagina with green soap under anæsthesia. Bichloride douches have found favor with some. The fact remains, however, that in many instances like the proverbial cat, the organism returns to discourage the patient and exasperate the physician.

The foregoing embrace the etiologic, the pathologic, and the therapeutic principles concerned in the common leucorrheas. Such a presentation necessarily lacks much in completeness; but after all, with the aid of well-grounded principles one is enabled to think straight and with an enlarged experience to interpret correctly the frequent variations in the clinical manifestations of these common conditions.

GONORRHOEA IN THE MALE*

By FREDERICK J. PARMENTER, M.D., BUFFALO, N. Y.

General practitioners will find the following outline to be helpful in recalling the procedures that are standard on the modern treatment of gonorrhoea in the male.

SYMPTOMS

- 1. Acute urethral discharge with positive
- 2. Normal frequency in voiding. Glass one, cloudy. Glass two, clear.

TREATMENT

1. Hygienic

Food handlers cease their occupation. Place all soiled dressings in paper bag and burn.

Thoroughly wash hands after handling genitals.

Have own soap and towel.

Reduce physical exertion to the minimum. No sexual excitement or contact.

No indulgence in alcoholics.

Plenty of rest, sleep, and fresh air.

A mild morning saline to insure a bowel movement.

Omit the following foods because of their oxalate content:

Pepper

Spices Tomatoes and their products

*Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

Milk and its products except butter Spinach

Asparagus Rhubarb

Mushrooms

Vinegar Chocolate

Cocoa

Strawberries

Peaches Gooseberries in any form

All soft drinks except oranges and lemons

Cream in tea or coffee allowed.

2. Medicinal

Water. A glassful every hour to keep urethra clean.

Urine very acid. Soda bicarb or any citrate. Urine very alkaline. Acid soda phos., Calcium chloride, ammonium chloride.

Urine to be kept neutral, i.c., slightly alkaline.

Urine burns. Oil Sandalwood caps. 60 E.

Drugs rarely necessary if sufficient water is drunk.

3. Local

Syringe. ¼oz. Becton & Dickinson. Injection. Amount 4-6 C.C.

Drugs. 5% of Silver nucleanate, silvol. 1/4% Protargol. 10% Neosilvol.

Technic. Patient voids. Draws 8 C.C. of solution in syringe. Places tip against mentus and gently injects NEARLY ALL in urethra. Leaving some in syringe so air will not drive solution to post urethra. Pinch meatus and hold solution for 5 minutes.

Time. Every 8 hours.

Irrigation. Not recommended. Il desired. Patient voids, Container with solution not higher than patient's shoul-Compress urethra just behind glans. Irrigate then release compression and irrigate urethra just touching tip against meatus and quickly withdrawing repeating each motion quickly. Pelouse method.

Solutions used. Potassium permanganate

1-6000. Neutral acriflavine 1-1000. Dressing. Sanitary bag. Gauze, NEVER cotton in bag.

When discharge stops give injections at 12 then 24 hour intervals. Then stop. Resume if discharge reappears.

Disease very acute and penis edematous. No local treatment. Paint penis with Tr. Metaphen. Soak in hot Sat. Sol. Boric acid. Resume treatment when better. Niazo tabs 2 T.I.D. P.C. as antisentic.

Causes of relapse. Alcoholic indulgence, sexual excitement, nocturnal emission,

lapses in diet.

Tests of cure. No discharge for 6 weeks. G. 1 and G. 2 clear. Secretion from prostate-vesicles normal. No discharge after passing 24 Fr. catheter, filling bladder with 1-10,000 sol, silver nitrate. removing catheter, patient voiding naturally, examining next day for discharge containing gonococci.

Causes of relapse bring no return of discharge. Repeat examination in a

Time of marriage. Has remained well for 6 months. Repeat examination and examine condom sample.

Complications. Acute post urethritis-

prostatitis-vesiculitis.

Sudden frequency - urgency -Symptoms. dysuria. Perineal discomfort. Voidings small. G. I and G. 2 cloudy. DIFFICULTY due to acute follicular

prostatitis, may result in abscess.

Treatment. Patient in bed. No local treatment. Keep bowels open. Push fluids. Hot sitz baths and rectal irrigations. Morphine-codeine or O & B suppos for pain. Indwelling catheter for acute retention. Perineal incision for abscess. Continue Niazo tabs. Resume injections when symptoms abate. No instrumentation or massage for a month.

Acute epididymitis

Symptoms. Perineal pain, crossing pelvis, down vas to epididymus. Chills, fever, prostration. Epididymus swollen, tender, very painful. Cessation of discharge,

Treatment. As for acute post urethritisprostatitis - vesiculitis with support to the scrotum. Apply moist heat or guiacol 4 C.C. in sweet oil, 60 C.C. with camels hair brush and cover with cotton. If abscess develops drain.

Peri-urethral abscess

Swelling upon the under surface of urethra.

Treatment. Paint with Tr. Metaphen and remove all pressure (suspensary). abscess forms, incisc skin only to avoid

Chordce indicates deep seated infection.

Stricture is apt to follow.

Treatment. Patient voids several times during the night. Sedatives if necessary.

DONT'S

Use any solution which irritates.

Cause pain in administering treatment or be rough.

Use sounds, etc., only after all acute symptoms have been absent 4 weeks.

Never use same finger cot on another patient. Rectal Gonorrhoea.

Be patient and take time.

THE ACCESSORY NASAL SINUSES IN SCARLET FEVER By DONALD SMYTHE CHILDS, M.D., SYRACUSE, N. Y.

From Department of Radiology, Syracuse University, Syracuse, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

LER says that scarlet fever is "an infectious disease characterized by a diffuse exanthem and an angina of variable intensity." While Anders and Boston say that the

same disease is "an acute infectious disease characterized by high fever, marked angina and a diffuse erythematous dermatitis." These authors do not class sinusitis among the complications, nor solution. Of this 8 cc. are used in a quart of water at night just before retiring. In severe cases a morning douche may also be taken.

The second indication is met by the liberal use of a powder in the vagina and the insertion of an elongated absorbent tampon. The powder aids in keeping the vagina dry and the tampon separates the vaginal walls and absorbs any exudate. The tampon remains 12 to 24 hours, its removal being followed by a douche. THE ACCESSORY NASAL SINUSES IN SCARLET FEVER By DONALD SMYTHE CHILDS, M.D., SYRACUSE, N. Y.

From Department of Radiology, Syracuse University, Syracuse, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

LER says that scarlet fever is "an infections disease characterized by a diffuse exanthem and an angina of variable intensity." While Anders and Boston say that the

same disease is "an acute infectious disease characterized by high fever, marked angina and a diffuse erythematous dermatitis." These authors do not class sinusitis among the complications, nor

do they mention it as a condition which accompanies scarlet fever. In fact, very few references to these two conditions considered together have been found.

Believing that sinusitis accompanies scarlet fever, a study done under the auspices of the Hendricks Research Fund of the College of Medicine, Syracuse University, in conjunction with the Nose and Throat and Pediatric Departments of the College as well as the Bureau of Communicable Diseases of the Syracuse Department of Health was undertaken. At this time, thanks and appreciation are given to each. Our study is not completed but is being continued. Several very interesting things have developed which seem worthy of recording at this time. A portion of our cases were reported at the meeting of the American Public Health Association in the Epidemiological Section, September 14, 1931, by Dr. A. C. Silverman, and to whom I am indebted for certain information incorporated in this report.

The study to this time consists of 383 cases of scarlet fever who were admitted to the City Hospital and examined there by each department participating in the study. The roentgenograms were made during the first week of the disease. A group of these were re-examined at a later date, having their study at about the twenty-eighth day of the disease. Double screens, 80 kvp, 25 inch target film distance, with 20 ma through the tube were used, and the patients exposed in the chinnose, nose-forehead and lateral positions. We did not attempt to take the sphenoids into consideration. The cases were first grouped as clear, hazed, dense, and opaque, but realizing that the shading of hazed and dense were perhaps a little too fine, these were combined. Study began in February. 1930, and still continues.

In but 9% of our cases were the sinuses found to be clear. 79% showed hazing and 12% opaque. These findings were not expected. We found that the frontals were not developed in 69 cases, or 18%; while there was unilateral development of the frontals in but 6 cases. The frontals were found to be clear in 110 cases. The most frequent lesion was found to be bilateral hazing of the maxillaries and ethmoids, which occurred in 30% or 123 cases. The next in frequency was bilateral hazing of the maxillaries - present in 27% or 104 cases. Pan sinusitis was present in 9% or 34 cases. The remaining cases were scattered through various combinations of sinus involvement. It is to be noted that maxillary invasion was present in well over two-thirds of all cases.

Ninety cases have been restudied, and in but

12% have we been able to find any roentgenographic evidence of improvement. 36% show no improvement and in over 50% there is definite evidence of progression or extension of the radiographic evidence.

Children in the 3-4 year old group had no clear sinuses, but it was noted in the 5-14 year old group that over 8% were clear; while in the older group the percentage of clear sinuses increased to 11-14%. Baulmer, quoted by Silverman, "concludes that the younger the clild the greater the likelihood that the sinuses will be pathologically involved in scarlet fever." The disease was almost evenly divided between boys and girls.

Thirty-three cases developed mastoiditis shown by roentgenograms and confirmed by surgery. In each of these cases there was roentgenographic evidence of sinusitis on the side of the mastoiditis, and in no case with clear sinuses did mastoiditis develop. Mastoiditis was found in the ratio of four to three in boys as compared with girls.

Quoting from Silverman-"Actual exploration of the sinuses would be of unquestioned value in diagnosis. This was done in only one instance and in this instance it diverged widely from the x-ray interpretation. A seven year old boy whose onset of scarlet fever occurred May 29th had his sinuses x-rayed five days later and the left antrum was reported dense. His was a very mild case, the temperature becoming normal on the fifth day. On the twenty-ninth day his nose culture was negative for hemolytic streptococci and aside from slight reddening of the nasal mucosa, no discharge was present. This was confirmed by the rhinologist. Two days later the x-ray was repeated and the left maxillary found still dense. Permission was obtained to puncture the antrum but no pus was obtained."

-We have had four cases who had roentgenographic evidence of pathology of the sinuses when released from the hospital, and from five to thirteen days later, either a brother or sister came down with scarlet fever.

Note is made of the fact that in this study there has been no crossing of infection. In view of the many difficulties in making the films, great credit must be given to the contagious disease technique and to the care used by the technician and nurses.

While it is appreciated that this study is not complete and the control groups of the various age periods are still too small to be of any great value, we believe that sinusitis is a very frequent pathological factor in scarlet fever, being present in 91% of our cases. Such sinusitis is not readily cleared, and when mastoiditis is a complication of scarlet fever, sinusitis will be found on the affected side.

EMPYEMA AS IT APPEARS TO THE INTERNIST* By JOHN J. ROONEY, M.D., ROCHESTER, N. Y.

MPYEMA is the collection of pus within the pleural cavity. It resembles peritonitis in that it usually results from direct extension of some neighboring infection. However, just as you may have a primary peritonitis, so is it conceivable empyema may occur, but these cases are relatively rare. The disease is uncommon in septicemias except as a terminal manifestation of an overwhelming infection. It occurs also from trauma, as in perforating wounds of the cliest wall during which infected material may be introduced into the plenral cavity, and particularly in those cases in which foreign bodies such as pieces of clothing, broken rib, bullets, etc., are left behind. Rupture of the resoplagus by fish-bone or other articles swallowed, or by instrumentation, direct extension of mediastinitis of whatever cause, rupture of a lung absecss, and extension of a purulent pericarditis are less common causes. Contignous suppurative processes in the abdominal cavity, such as sub-phrenic or liver abscess or perinephritie abscess, may spread through the diaphragm to invade the pleura. But by far the most common underlying condition disposing the individual to the development of empyema is pneumonia, lobar and bronchial,

The incidence of empyema varies greatly. It is more common during the late winter months, when pneumonia is more prevalent. It is more common when there is an increase of upper respiratory infections, especially during epidemics of these diseases. This was brought home with striking force during the Great War, when large numbers of eases of empyema occurred among the soldiers in the cantonments. This increase became so alarming that the Surgeon General sent out questionnaires to gather data concerning the causes and appointed a commission to study the question. They were of the opinion that outbreaks of measles and influenza, which in places reached epidemic proportions, had no direct causative bearing upon the incidence of empyema, but the relative presence of upper respiratory infections such as pharyngitis, tonsilitis, bronchitis, etc., ran parallel to the increase in occurrence of empyema. That is to say, the incidence of empyema following pneumonia increased where there was, in the same cantonment or group, a concomitant increase of acute upper respiratory diseases. Empyema occurs oftener in children than in adults, and in the negro oftener than in the white. As to the incidence of the various causative organisms, I shall say little, since the bacteriology is being discussed in another paper. The relative importance of the pneumococcus versus the streptococcus varies with the different sources of statistics and the different years. For example,

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

Heuer reports 339 cases following pneumonia at the Johns Hopkins Hospital for the thirty-two years from 1889 to 1921. In 153 cases, or 45%, pucumococcus was the etiological agent; in 34 cases, or 10%, the streptococcus; in 23 cases, or 7%, the staphylococcus. Cook's series of 103 cases at the Cincinnati General Hospital for five vears from 1922 to 1927 shows 43% were caused by the streptococcus, 31% by the pneumococcus, and 22% by the staphylococcus. It is to be remembered these latter were from all causes, postmenmonic and otherwise. In 450 fatal cases occurring during the World War, the streptococcus was responsible in 81%, the pneumococcus in 17%, and the staphylococcus in 2%. None of these series reports mixed infections, but they do occasionally occur. I mean mixed pyogenic infections and not mixed tuberculous and pyogenic, which also occurs. It is perhaps not inappropriate to add here that although usually the organism causing the pneumonitis is the one responsible for the empyema, this is not always the case, for instances occur where the pneumonia may be due to a pneumococcus and the empyema to a streptococcus, and vice versa. I believe that a grouping of large series of cases from different sources over a long period of years will reveal the pneumococcus the most common organism. Of the pneumococci types I and IV predominate. Pneumonia due to type I is particularly likely to be complicated by empyema. The streptococcus comes second, and the staphyloeoccus third. Other pyogenic organisms that are found causing empyema, such as the influenza bacillus, typhoid bacillus, colou bacillus, gonococcus, streptothrix, amœbæ, trail along far in the rear.

No very definite figure can be given as to the incidence of empyena during and following pneumonia, but from immerous different sources the figure varies from 2% to 7%. That is to say, anywhere from 2% to 7% of cases of pneumonia develop a collection of pus in the pleural cavity. Not all of these come to operation. Some are found at autopsy, while others recover with siminary to the control of the control of

ple aspiration.

The diagnosis of a typical case occurring with lobar pneumonia is not difficult. The patient, on or about the seventh day of his illness, has his crisis, follows along from one to four days with normal or sub-normal temperature and slowed pulse rate, when his pulse and temperature rise again. Or his pneumonia may terminate by lysis, but the temperature and pulse do not quite approach the normal, and after a few days of reduction; start rising again. His appearance changes from that of an acutely ill patient to one chronically sick. He is not so uncomfortable as he was with his pneumonia, but he runs an irregular fever from 100 degrees to 103 degrees F.

with rather profuse sweats. Cyanosis and cough usually are not prominent, although in some cases the latter may be very annoying. His white blood count reveals a leucocytosis with an increase of the polymorphonuclears, but these increases are not so marked as they were during the pneumo-Physical signs change in that part of the chest under which the fluid has accumulated. Dullness changes to flatness; tactile fremitus, breath and voice sounds diminish in intensity, often to the point of being absent. There may be some edema of the chest wall and dilatation of the venules of the skin, lessened respiratory excursion of the involved side, a fullness of the intercostal spaces together with tenderness over the area of the fluid. If the fluid is sufficient in amount, particularly when located in the left chest, there is displacement of the heart to the opposite side, or when in the lower portion of the right chest, a downward shifting of the liver. There may be a thin area above the level of the fluid where the lung is partially compressed over which there will be dullness, perhaps with a tympanitic quality, together with breath and voice sounds of broncho-vesicular character. Above this will be signs of a normal lung. The other side of the chest will show a hyperresonance with exaggerated breath and voice sounds, due to its attempted compensation for reduced capacity of the lung on the involved side. Grocco's triangle may be demonstrated upon the sound side but I believe its presence or absence is unimportant. In these typical cases where the pneumococcus is found in the fluid, the pus develops late in the primary disease, accumulates slowly, and shows a marked tendency to encapsulate early.

The above cases rarely present a problem of diagnosis, although in some the location of the pus may not be found as readily as might be expected. But those cases due to the streptococcus may be very confusing. With the latter the pus accumulates very quickly and in large quantities early during the disease, which in the great majority of cases is a streptococcus broncho-pneu-This exudation may occur as early as the second or third day and often is present when the physician is first called in to see the patient. With many of these cases the symptoms of the pneumonia, except for the cough, oftentimes not very productive at first, are absent. The signs of fluid in the chest are very prominent, masking the signs of the underlying pneumonia, and the diagnosis of primary empyema is made. Usually, however, the opposite is true. The signs are those of consolidation, dullness, bronchial breath and voice, and sometimes even tactile fremitus over a large area in one, or not infrequently in both chests. These signs are particularly prominent if a few of the larger bronchii are temporarily plugged by mucus. Having the patient give a few hard coughs before the examination of the chest helps clear up this difficulty.

However, in many of these cases, the signs and x-ray films, although suspicious, are not convincing, and a diagnostic thoracentesis establishes the diagnosis.

There are no one or two physical signs that definitely are pathogpneumonic of fluid in the chest, whether it be an exudate or transudate. Displacement of the heart and other mediastinal structures, when it is present, is the most important, but absence of displacement does not rule out hydrothorax. As stated previously, the fluid must be rather large in amount, especially if in the right pleural cavity, since the heart does not shift so readily to the left as it does to the right. Absence of tactile fremitus and presence of absolute flatness in contradistinction to dullness are the next best guides of the physical signs. However, reliance should not be placed upon these for establishing the diagnosis. The important criteria in determining the underlying pathology is the relative consideration of all the signs together and particularly the changes in them that occur from one examination to the next.

Usually the diagnosis can be made without the use of the roentgenogram. The history of the primary illness, the physical signs, and thoracentesis are sufficient in the vast majority of cases. In some the x-ray is of little or no aid. These films are usually made with the patient flat on his back and frequently with a portable machine. This, together with the fact that it is difficult to get good respiratory cooperation of the patient, does not render the roentgenological diagnosis any too easy. The presence of a thickened pleura or a thin layer of fluid which when prone covers the whole posterior surface of the lung is difficult to interpret under these conditions. Also the presence of a relatively small amount in the lower inner posterior portion of the left chest may be totally obscured by the heart shadow unless lateral films are also taken. On the other hand, the x-ray may be of the greatest aid in discovering deep-seated lesions, for example in encapsulated interlobar empyema and in those collections along the mediastinum and those situated upon the dome of the diaphragm. It, too, is of assistance sometimes in determining whether the disease is above or just below the diaphragm.

In the differential diagnosis the history is very important. There are conditions occasionally occurring which may be confused with empyema. Echinococcus cyst of the lung is one. Although rare in our section, we had an instance of it two years ago in Rochester. In this disease the history of no recent acute respiratory infection or of the patient coming from a country where it is prevalent is a significant lead. The complement fixation test will usually establish the cause of the illness. If not, the aspirated fluid invariably will show hooklets. Actinomycosis and blastomycosis will usually give a history of and present signs of a similar infection in another part of the body.

or there may be a draining sinus in the chest wall from the fluid of which the organism can be demonstrated. Cases of chronically thickened plenra, serofibrinous plenrisy, and plenrisy with effusion can be distinguished by thoracentesis. Non-inflammatory diseases such as malignancy or malignant metastases of the lungs and pleura, which sometimes give signs of fluid in the plcural cavity, may be differentiated from empyema by the history, by the lack of febrile symptoms, absence of leucocytosis, and finally by the x-ray. In the conditions below the diaphragm, especially abscess of the liver, sub-phrenic abscess or perinephritic abscess, a careful history will usually elicit a previous recent attack of acute appendicitis or ruptured gastrie ulcer or an illness in the Tropics that was probably amorbic dysentery, or, as in the case of perinephritic abscess, some urinary symptoms and the finding of ous in the urine. In these conditions the a-ray will be a distinct help when the history is sufficient.

I have purposely left to the last the discussion of the most important aid in diagnosis, thoracentesis. This is a simple and in good hands a painless and harmless procedure. It can be done in the home. With good technique, no sterile gloves or drapes are necessary. A small syringe and needle for novocaine anæsthesia of the skin and intercostal space, a larger syringe and needle for the aspiration, some soap and water with alcohol or iodin for skin sterilization, are the only requirements. A sterile test tube for culture purposes should be handy. A hypodermic of morphine, one-half hour previously, renders it easier for the patient. The aspirating needle should be large gauge. The piston should fit tightly into the syringe, preferably with a seal of the water in which it was boiled. The spot chosen for needling should be where the signs and tenderness and x-ray, if done, show it most likely to be located, and not in the sixth interspace in the mid-axillary line, or the eighth space in the scapular line, simply because these are the sites most frequently used, although they should be chosen if there appears to be no definite choice. Sometimes it is difficult to determine whether the needle has become plugged or whether the point is free in the pleural cavity. This may be obviated by having a small amount of sterile water in the syringe, or by not having the piston fully pressed into the syringe, so that there is some air This will be sucked into the free contained. plenral cavity, due to the difference in pressure. It is always wise, after a dry tap, to see if the needle was plugged. Sometimes thick pus or fibrin will do it. Occasionally in introducing the needle the lumen will be plugged by a small piece of skin which it has gonged out during the introduction. The fluid obtained, even if it appears to be only a small amount of blood, should be examined microscopically and cultured. As soon as the diagnosis is established, the surgeon should be called into consultation to allow him to select the time of operation and the type of drainage he desires to institute.

If the general practitioner or internist regards every case of pneumonia as a possible subject of empyema, the diagnosis will be made oftener. Pneumonias existing longer than ten days should be regarded as suspicious. Hospital cases of undiagnosed empyema continue to come to autopsy, nucli to the embarrassment of the attending physician. Undoubtedly greater numbers occur in homes which never come to post-mortem examination. With careful histories and physical examination, together with the aid of the x-ray and judicious use of thoracentesis, less deaths will be attributed to so-called "unresolved pneumonia" and more people will be walking around with drainage scars in their chest wall.

THE CHOICE OF TREATMENT IN ACUTE EMPYEMA* By CARL EGGERS, M.D., NEW YORK, N. Y.

E MPYEMA usually complicates or follows pneumonia, but it may be secondary to a lung abscess, or it may result from external injury, or be part of a general septic process.

The pus may be situated anywhere within the pleural cavity, though it usually settles in the lower part of the chest. It may be thin or thick creamy in character. It may be present in very large quantity, filling one side and displacing the mediastinum to the opposite side, or it may form a small encapsulated pocket situated somewhere

between the lung and the chest wall, or in the mediastinum, or between the lung and the diaphragm or between two lobes. At times there may be an empyema in both pleural cavities at the same time. Occasionally it is associated with the presence of air, forming a pyopneumothorax.

The organisms usually found in the pus are pneumococci, streptococci, or staphylococci, but occasionally one finds colon bacilli, influenza bacilli, or a mixed infection.

Empyema may exist alone as a complication or sequella of pneumonia, or one or several other complications may be present at the same time,

^{*} Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

such as otitis media, pericarditis, joint affections, cellulitis, or abscess. At times a pneumonic process may still be active on the same or the opposite side.

If one bears in mind all these facts it will at once be apparent that the treatment may have to vary, or at any rate that it does not seem wise to make one method fit all the different conditions. If in addition to that one bears in mind that the course of empyema and its prognosis may vary not alone with the treatment employed but that it varies in different years and in different seasons, and that it depends largely on the age of the patients, the type of organism, the virulence of organisms, and whether it follows a primary or a secondary broncho pneumonia, then it becomes apparent that one must individualize and select not alone the proper procedure, but also the proper time to operate. Only in this way is it possible to attain the best results.

Some form of drainage to rid the body of pus and to allow the lung to re-expand is indicated. In other parts of the body such collections of pus are treated by simple incision and drainage without other considerations. In many empyema cases the conditions are almost as simple, but in others the rigidity of the thorax, and the effect on respiration and circulation of an open pneumothorax have to be considered and in many cases form an important problem. The consideration of these different points has led to the adoption of the various forms of treatment employed.

It may be said that as a rule empyema should not be looked upon as an emergency. There is usually ample time to await the laboratory report on the culture of the pus obtained on puncture. One should know all about the patient before deciding on the form of treatment to be employed.

METHODS OF TREATMENT 1. Aspiration

The simplest operative procedure is aspiration. By this is meant removing the pus either with a syringe or some form of aspirator, preferably the Potain, which removes the fluid by suction after a negative pressure chamber has been created in a bottle. No air is allowed to enter the cliest. The method is indicated when it becomes necessary to remove fluid while the pneumonia is still active. The object is to bridge over a critical period during which it is considered inadvisable to perform an operation. It is also of value during the early stages of bilateral empyema, or in any extensive exudate before the pus has become thick, and before adhesions have formed. If one understands its limitations, and does not prolong its use unduly, it is at times very valuable. Though one or several aspirations occasionally lead to a cure, even in the presence of a positive culture, the method should not be employed to attempt a cure, or even to use it as long as possible. A definite objective is followed, namely to rid the body of an infected fluid early in the course of a pneumonia until the process in the lungs has subsided and the fluid been walled off. As soon as this stage is reached, an operation should be performed.

There is a definite danger in continuing aspirations too long. The teaching that too early an operation in empyema is not advisable has led some men to carry out aspirations too long, thereby seriously endangering their patient's life from septic absorption. I want to warn against this. As soon as there is pus which on standing shows about 50% sediment, it should be evacuated by operation.

2. Closed Methods of Drainage

Closed drainage is considered more physiological than open drainage in that it maintains negative pressure within the empyema cavity and thereby least disturbs respiration. This is true and it therefore finds its greatest application in those septic cases in which, early in a pneumonia, the presence of the fluid itself is considered a menace to the patient. It is here used to bridge over the critical period until the pneumonia has subsided and adhesions have formed. Closed drainage is also valuable in all cases with extensive exudates, with bilateral empyema, and in patients with a pyopneumothorax.

Some surgeons prefer this method to all others and use it as a routine until healing results, while others use it only for a week or ten days and then convert the drainage into an open one.

The simplest procedure, and the one most often employed, is to insert a trocar into the eighth or ninth interspace after infiltrating the tissues with ½% Novocaine and making a small skin incision to facilitate its introduction. After withdrawing the obturator, the catheter or drainage tube with its outer end clamped, is quickly inserted and the trocar then removed. The soft tissues fit snugly around the tube and prevent the entrance of air. A small cuff of rubber tubing is fastened over the catheter close to the skin, and a safety pin passed through this. After that a small piece of gauze is placed under the pin and two narrow strips of adhesive plaster are fastened over it to prevent slipping.

The further treatment depends on whether one desires continuous or intermittent drainage. In large exudates it is advisable to evacuate slowly, perhaps 250 ce. at a time at intervals of several hours. The tube is therefore kept closed with a clamp or a clip, in the intervals. As soon as all the pus has been evacuated the drainage may be made continuous. A longer tube is therefore connected with the catheter and led into a drainage bottle under the bed with the end of the tube under the fluid level to insure closed drainage. The ease of performance, the minimum disturbance it causes the patient, the facility in irrigating the

cavity, and the avoidance of large pus soaked dressings, commend the method most highly.

Many surgeous have their own little pet device or appliance by means of which they attain good results, while in the hands of others these same devices frequently lead to failures. The result has been that innumerable methods of closed drainage have been proposed only to be later discarded. At any rate though elosed drainage has been used for years, it has not been universally adopted as a routine operation. The reason for this is that it has failed in certain important respeets, the elife of which are inadequate drainage and inability to dispose of large fibrin clots. Owing to the small ealibre of drainage tube it is a common experience to have blocking of the tube, with retention. A great deal of attention is required to insure a constant flow. Damming back of pus leading to reinfection of the cavity is the To overcome this one may add an irrigating system to the drainage system in the form of the simple apparatus shown in Fig. 1. One limb of a Y tube is attached to the catheter emerging from the chest, while the other connects with the tube of an irrigating bottle elevated above the The stem of the Y connects with the tube leading to the drainage bottle under the bed. By clamping the lower tube, fluid in any desired amount may be allowed to run into the empyenia eavity, and kept there a few minutes to aid in sterilization. The clamp on the lower tube is then removed and placed on the upper one, which results in prompt evacuation of the empyema eavity. If one uses Dakin solution in this way every two or three hours, fibrin clots will be dissolved and gradual sterilization of the cavity brought about.

The narrow intercostal space in some patients, and especially in children, does not permit of the introduction of a large trocar, If, therefore, closed drainage by means of a larger tube is desired one or two methods are available. One may make an intereostal incision, insert any size tube desired, or a mushroom catheter, close the soft tissues around it and then connect the tube with the irrigating and drainage tubes as shown in Fig. 1, or one may resect a small piece of rib and insert the tube through the floor of the rib bed. This has the advantage that large open drainage may be established by simply reopening the wound after the need for closed drainage no longer exists.

With any of these procedures real closed drainage may be maintained for from five to ten days. After that a little infection along the drainage tube may loosen it somewhat and although one continues to speak of closed drainage because the pus is evacuated through a tube into a container there is no longer any actual negative pressure in the empyema cavity. By this time the need for negative pressure is over anyway and one may

easily convert the wound into an open one, without discomfort or danger to the patient.

3. Open Metitods of Drainage.

By this is meant incision and drainage as it is practiced for pus collections in other parts of the body. If one visualizes an empyema as an abscess of the plenra surrounded by an abscess wall which covers the lung, lines the chest wall and forms a protective barrier against the unmvolved portions of the plenra, this method of treatment appeals to one as the ideal one, for it gives free exit to the pus and enables the compressed lung to re-expand. The methods of approach vary

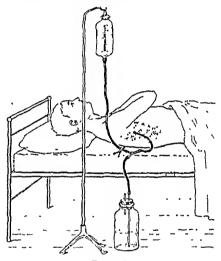

FIGURE 1.

from an intereostal incision, or the resection of a small portion of one or two ribs, to the wide open incision with packing of the eavity advocated by Dr. John F. Connors. In all of these operations pus is given free exit, perhaps supplemented by irrigations with antiseptic solutions depending on the operator. The operation is easily performed under local anaesthesia and may be done at the hospital or at home. Little or no embarrassment of respiration results, on the contrary, breathing becomes easier with free drainage of the infected material and subsequent diminished absorption. The patient may be out of bed as soon as his general condition permits, and his position in bed may be changed as desired and as is compatible with his confort.

No special appliance or apparatus is required, for a drainage tube is easily procured or improvised. The after treatment is usually very sim-

ple. Drainage is continuous and easily maintained. With an empyema drained at the proper place, early healing is favored by keeping the cavity empty, sterilizing it, and preventing damning back of pus. The lung will gradually expand, the formation of a thick disabling pleura will be prevented, and as a result the danger of recurrence and chronicity is minimized.

From what has been said it is apparent that this type of operation is indicated in all those cases of empyema in which the pneumonia has subsided, and in which the pus, whether large or small in amount, has become encapsulated by surrounding adhesions. There is no danger connected with the operation if ordinary surgical principles are observed. All steps are performed under guidance of the eye, bleeding is easily controlled, and pus and fibrin clots can be evacuated. There is no danger of an open pneumothorax because the lung is prevented from collapsing by the adhesions holding it to the cliest wall.

SUMMARY

There exists at present some confusion regarding the best routine method of procedure in acute empyema. The proper treatment of empyema, in all its phases, requires a knowledge and an appreciation of the physiology of normal respiration and also of the variations in the presence of disease. No one method will always give uniformly good results, and no attempt should be made to make a case fit a given method of treatment. On the contrary, that treatment which will most likely restore the patient to health in the shortest time should be adpoted in each case. Individualization is the keynote of the successful treatment of emnyema. Experience has shown that there is such a thing as a common type of empyema, following pnemococcus pneumonia, in which the pus collects in the lower part of the chest. It becomes walled off early and the costopleural angle becomes obliterated by adhesion of the diaphragm to the chest wall. Intercostal incision in the eighth or ninth space or the resection of a portion of the eighth or ninth rib will place the drainage at the dependent part of the cavity.

Simple open drainage or the addition of irrigations, preferably with surgical solution of chlorinated soda (Dakin solution), constitutes the after treatment. By far the larger number of all

empyema cases conform to this type.

Taking this as a basis, one may modify the treatment as indicated in a given case. If there is an unusually large amount of fluid, as is so often found in the septic streptococcus cases, and it is felt that the presence and absorption of this fluid itself, regardless of the stage of the pneumonia, is dangerous to the patient, one of two courses may be followed:

- 1. The fluid may be aspirated, and this may be repeated as often as the thorax refills, until the pneumonia has subsided. Coincident with resolution, the fluid has usually become pus and has become walled off. A simple drainage opening may then be made, as advocated above, and the case treated the same as a pneumococcus empyema.
- 2. If more urgent treatment is demanded one may establish closed drainage as described above, either by means of the trocar catheter method, or by the insertion of a tube through an intercostal incision. Irrigations may be added by making use of the apparatus shown in Fig. 1. One may continue this method until a cure results or only sufficiently long to bridge over the period of emergency and then convert the drainage into an open one.

The aim is to keep the cavity empty and to bring about sterility, for this is the secret of healing. This sterility is best obtained by open drainage, perhaps favored by irrigation with antiseptic solutions. I believe that the only safe healing for an empyema is by obliteration of the cavity. The two opposing layers should adhere, and they will adhere just as soon as the surfaces are sterile. Such an obliteration is the best guarantee against recurrence and chronicity.

AVOIDANCE OF CHRONIC EMPYEMA

No consideration of the treatment of acute empyema is complete which does not visualize and try to avoid the development of chronic empyema. In spite of all that has been written and taught patients with chronic empyema present themselves for treatment. In some of these the condition was unavoidable in that factors operated which were beyond the surgeon's control, but in the large majority the development of a chronic state was due to lack of recognition of the causes leading to chronicity. The most common of these is imperfect or inadequate drainage through a narrow sinus, allowing damming back of pus, repeated re-infection of the cavity, and the development of a thick unyielding pleura. The next most frequent cause is an improperly placed drainage opening, one not at the dependent part of the cavity. Another common cause is too early operation, allowing the lung to collapse at a time when no or only a few thin adhesions have formed. All these causes argue for delay in operating until the pneumonia has subsided and the fluid has been walled off. Once this stage is reached, which usually coincides with the development of thick pus, good drainage should be established and maintained. These are the most important points in bringing about an early cure and in preventing recurrences and chronic cavities.

FURTHER EXPERIENCES IN THE TREATMENT OF EMPYEMA THORACIS BY PACKING*

By JOHN F CONNORS, M D, NEW YORK, N Y

IN July, 1931, we published a new method of treatment of pleural suppuration and presented reports of 35 cases. We are now presenting the results in 23 cases of empreina thoracis and in 11 cases of other types of pleural suppuration which have been operated

upon since the first report Pre-operative Preparation of the Patient Prior to the World War the procedure m empyema was to operate as soon as pus was discovered Since the war the dictum has been to wait until the pus becomes thick However we have carried the procedure one step further and, unless there are signs of rapid downward progression, operation is postponed until the time when the patient's condition is improved. We wait, therefore, not only until the pus is thick but until the patient's resistance is strengthened by daily pleural taps, by allowing time for the subsidence of any possible underlying pulmonary infection, by forcing nourishment and fluids, and, if necessary, by transfusion of blood We have found anemia, dessication, and malnutrition almost constant when cases are brought to us for operation Pre operative preparation cannot be stressed too much for it is one of the most important factors in the determination of operative mortality. Another important factor in the reduction of our operative mortality is that all cases of empyema at the Harlem Hospital are cared for by a special group rather than being disseminated among several surgical groups as they were formerly This makes for standardization of treatment. greater interest and expertness in care as would be expected when any special type of case is cared for by one group of men

The Operative Procedure -The procedure is essentially the same as described in our first report, although several minor changes have been made. The patient is placed in the recumbent position with the unaffected side npon the table The incision is made according to the position and extent of the empyema Usually it is placed at a dependent portion About two and one-half inches of two adia cent ribs are removed subperiosteally intervening muscles and vessels are now grasped with artery clamps and are removed en masse The severed ends are ligated close to the severed ends of ribs

When pus is located with an aspirating syringe, the opening produced by the needle is made larger gradually and slowly. A grooved

director is inserted beside the needle an open mg is made large enough to admit the nozzle of an aspirating apparatus and as far as possible pus is removed. The orifice in the pleural cavity is then slowly opened widely but great care is taken to cover the orifice if the patient experiences distress with the sudden entrance of air into the pleural cavity. The hole in the chest wall which is finally obtained is approxi mately two mehes in diameter. Through it, with the aid of the Cameron light, the greater part of the pleural cavity may be investigated, adlications between pockets of pus may be broken down and fibrin and pus may be removed If the empyema is not complete, care is taken not to invade the uncontaminated portion of pleura by breaking down the wall of the cavity

In packing the pleural cavity plain gauze is used It is prepared from the wide bandage roll by folding it longitudinally until it is about two inches wide. The amount of gauze used varies with the size of the cavity some cases we have used thirty yards of packing. We have abandoned the use of iodoform gauze because in a few cases it seemed to produce toxic symptoms, was more expensive and proved no more efficacious than plain gauze With a curved sponge forceps, the gauze is introduced into the cavity, particular attention being paid to the region of the apex of the lung and to the sulci formed by the lung and the chest wall More and more gauze is introduced, filling the entire cavity and by digit-al pressure is firinly packed. The edges of the skin wound are held apart by gauze and the cut surfaces are protected by vaselinized A dry dressing completes the proced ure During the operation there is a continu ous intravenous drip of physiological saline solution which is continued as the individual requires

Post-operative Care—Patients are well covered and so placed in the wards as to avoid undue exposure when returned from the operating room. Those who are dyspnoeic or cyanotic are placed in the oxygen chamber or in an oxygen tent where they are kept until they are out of danger. We have found oxygen, when properly administered in tent or chamber a valuable aid. Forced fluids and nourishment and transfusion of blood are continued after operation, as before. Whiskey is given—one or two offices three times daily—especially to those who are accustomed to it Gradually we have been getting the patients out of bed curier and earher, frequently as

^{*} Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo N Y May 24, 1932

soon as the second day post-operative. Those patients who are not markedly prostrated or febrile, shorten their convalescence when they move about and are able to take advantage of outdoor sunshine and air. We urge our patients to blow into Wolf bottles and balloons and to cough and exercise, though little cooperation is obtained in this respect. In spite of this, however, the expansion of the lunch has been excellent as a rule.

The packing was removed in two days and in each case (except one) of our new series of 23 cases was not replaced with fresh packing. In several instances we removed the packing one day after operation in order to demonstrate to visiting surgeons the condition of the lung and pleura. In every case, except one, the parietal and visceral pleuras were clean and of pink or light red color. The one exception required a second packing. Packing acts by debriding the pleura of pus and fibrin by means of pressure and absorption. rule the lung expanded freely, coming up to, or nearly to, the hole in the chest wall after coughing or with vigorous respiration. Thereafter the purulent discharge was minimal, being no more than is expected in a case of a large clean granulating surface. No tubes and no irrigation are ever introduced into the pleural cavity. Not only are these not necessary but we have found them irritating and capable of maintaining a high fever over a long period of time. Superficial gauze dressings are applied every day or every other day, and our only care is the maintenance of the hole in the chest wall at a diameter of approximately three-quarters of an inch until the lung This is accomhas completely expanded. plished by the introduction of the finger through the orifice down to the pleural cavity.

COMMENT UPON STATISTICAL DATA

Deaths.—The first death was of extraordinary interest and in our series, unique. The patient, Albert C., 24 years old, was admitted to the hospital May 6, 1931, with a diagnosis of pleurisy with effusion, left chest. On account of the large amount of fluid in the pleural cavity, the possibility of an underlying pulmonary infection could not be determined. The fluid became more purulent and in six days after admission he was operated upon in the typical fashion which we have described. For three days post-operative he had an elevation of temperature and then for seven days further he had a normal temperature; he felt very well, the pleural cavity was quite clean, the lung was almost completely expanded and he was about ready for discharge. On the 10th day post-operative he developed an upper respiratory infection which rapidly spread to

his right lung and pleura. He became markedly prostrated with high fever, rapid pulse. and dyspnoea. Here was a case of an overwhelming infection invading the lung and pleura opposite to the side upon which operation had been performed. On May 22, 775 c.c. of thin purulent fluid was aspirated from the right pleural cavity and on the following day 500 c.c. of fluid was removed. Early on Mav 24, the patient died. The culture of the pus from the left side which had been operated upon showed staphylococcus albus, while the smear of fluid aspirated from the right chest revealed streptococci in short chains. sidering the circumstances, this is hardly an operative death but it is included as such.

The second patient was admitted to the hospital March 4, 1932, on account of a miscarriage. Three days later she developed pneumonia followed by empyema. She was operated upon May 13, 1932, and died the same day. Just prior to operation her condition was fair in spite of the long standing infection and a cardiac valvular disease. Operation was performed under local anesthesia. An empyema occupying about half the pleural cavity was found. Before operation a hemoglobin determination was made. It was 50%. Immediately after the operation the patient's condition continued fair but her pulse was more rapid and weaker. On account of the anemia and operative shock an immediate blood transfusion was ordered. Unfortunately this order was not carried out and the patient died five hours later.

Tuberculous Pyopneumothorax.—Both patients who were operated upon died. We have decided to abandon the packing procedure for cases of tuberculosis. The sudden disturbance of the infected lung of a very sick patient with dissemination of infection has been too apparent in this series, and in the series already published, to allow continuance of the packing.

Ruptured Lung Abscess.—The two cases of ruptured lung abscess reached the thoracic service long after rupture and were in extremis. One patient was being observed for a lung abscess which occurred after operation for appendicitis at another hospital. days after rupture of the abscess she was transferred for operation, was operated upon, and died the same day. The other patient was one who was admitted March 13, 1931, with a bullet wound in the neck and in the floor of the mouth. She developed an ill-smelling gangrene in the region of the wound with crepitation on palpation, and later a diffuse pulmonary suppuration. Two days before she was operated upon there was rupture of the pulmonary suppuration into the pleural cavity. Aspiration revealed diffuse foul smelling pusThe patient died on the same day Rupture of such pulmonary supportation into the pleural cavity is at any time a serious condition but when operated upon late presents a rather hopeless prognosis

Chronic Infected Pleural Carty—Of the seven cases which were treated with packing, three were cases of infected hemothorax following penetrating stab wound of the chest, two were cases of chronic infected cavity following operation in our first series in which the uncontaminated pleura was entered, one case had been operated upon at another hospital one year prior to admission to the Harlem Hospital and in which the pleural cavity had failed to close due to a piece of rubber drain which we found at operation, and one case of pyopicumothorax with thickened walls and several bronchial fistulae. The case which did not respond to treatment was the last

One of the cases of infected hemothorax showed a really remarkable response to packing. The patient was stabbed in the left chest February 8, 1931, developed a hemothorax which soon became infected. The pyothorax was then drained through a stab wound at a dependent portion of the pleural cavity spite of drainage and irrigation with Dakin's solution, the hing remained fixed close to the mediastinum for five months. At the end of this period decortication of the lung was de-A prehumary tight packing of eided upon the pleural cavity was performed with the sole idea of debriding the pleura of pus and fibrin In two days the packing was removed and to our amazement and satisfaction the lung was seen to expand for the first time in five months. and so rapidly continued to expand that in one month she was cured. No decortication was necessary The other cases ware not so startling in recovery but slowly and surely re sponded to treatment

Post operative Complications In general the post operative course is extremely unevent-One convalescence was marred by a diphtheretic wound infection. The patient was a child operated upon in the routine way. Two days afterwards the packing was removed and none was reinserted. The wound appeared clean and light red in color Five days postoperative the temperature rose to 103 degrees and the patient was markedly prostrated Careful physical evamination revealed no abnormalities except for the condition of the wound which was dull grev in appearance, quite in contrast to the clean pink or red color we are accustomed to see The condition suggested diphtheria and a culture confirmed this diagnosis Antitoxin was administered and the pseudo membrane cleared up, though the culture was positive for three days. The

source of the diphtheria bacilli was not iscer tained although cultures were made from the nose and throat of the patient and of each in dividual who had come in contact with her Convalescence from that time was slower than usual

In the cases of broneho cutaneous fistula one was allowed to close after three months of dramage, while in the other, dramage is still maintained five months post operative be cause of cavitation in the lung still demonstrated by the state of the lung still demonstrated.

strated by hipsodol injection

The statisties concerning age incidence, the type of empyema, and the bacteriology merely serve to emphasize the fact that in cises in which the patient receives meticulous pre- and post-operative care, the procedure of packing the pleural cavity in empyema takes no cognizance of any differences in age, type, or bacteria but produces excellent results in practically any case

The length of stay in the hospital has been greatly shortened. Most of our eases are ready for discharge in two weeks after operation, although, of course, further dressings are required. Patients frequently leave our control after discharge from the hospital and for this reason we have frequently kept them longer than otherwise necessary in order to make sure they are eared for properly. No ease is discharged until we are sure that there is no change for complication.

The incidence of post-operative fever is striking Thirteen of our 23 eases were afrebile within a week after operation and within two weeks 18 were afrebile. This compares very favorably with other methods of treatment with tube drainage and irrigation in which a daily rise in temperature may be expected for a month or six weeks and occasionally for two or more months. The tight packing reduces fever by successfully removing the causes and the products of pleural inflammation.

The operative procedure as at present carried out has no objectionable features. If it appears to be an extensive operation, one must remember that no operation should be considered extensive that produces a rapid restoration of function. Its advantages are many and in naming them we quote from our former communication.

The Advantages of the Packing Method

1 The pleural cavity is cleaned within twenty four hours and remains grossly clean until the cure is effected. This phenomenon is so striking that it is difficult for the uninitiated to believe it possible until it is seen

2 The ease of management post-operatively by the surgeon By the old method change of dressings daily or twice daily was necessary or else extensive apparatuses were employed

N. Y. State J. M. February 1, 1933

Even with the simpler procedures close attention to details was necessary. By this method dressings are changed at comparatively infrequent intervals and may even be forgotten for

several days.

3. The introduction of tubes is unnecessary, and therefore, a source of pleural irritation is removed. It is well known that drainage will continue as long as a tube is allowed to remain in a sinus. It is also noteworthy that no case of osteomyelitis of the rib developed in the cases since there was no tube to rub for days against a rib adjacent to the thoracotomy wound.

4. It prevents the discomfort which may be due to a mobile mediastinum by fixing it. In several cases when the tight packing was removed discomfort was experienced which was relieved by the re-insertion of the packing.

5. The large thoracotomy wound with the help of the Cameron light permits a perfect inspection of the pleural cavity and allows the operator to remove all fibrin and break up the necessary adhesions and pockets. And not least interesting it has allowed a clear view of the mechanism of the cure of the empyema cavity and has helped improve the methods directed toward cure.

STATISTICAL SUMMARY OF SECOND SERIES OF EMPYEMA

23 cases of true empyema with 2 deaths one death of operative shock one death of intercurrent disease

2 cases of tuberculous pyopneumothorax, 2 deaths

2 cases of ruptured lung abscess, 2 deaths 7 cases of so called chronic empyema cavities with 6 cures

Post-operative Complication:

1 case of wound diphtheria

2 cases of lung necrosis with bronchocutaneous fistula

Disease Preceding the Empyema:

18 cases of pneumonia 1 case of acute brouchitis 1 case of plenrisy with effusion

3 cases of pulmonary infection following abdominal operation

(It is possible that all were cases of pnenmonia, though variously diagnosed.)

THE PROPHYLACTIC USE OF THE PESSARY IN THE PUERPERIUM* By LOUIS A. SIEGEL, M.D., BUFFALO, N. Y.

REAT advances have been made in obstetrics in the past twenty-five years. This has led to the introduction of many new ideas regarding care during the prenatal and

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

labor periods. The expectant mother receives prenatal care early. This affords an opportunity for studying the general physical condition, the kidney and heart functions, so that the complications of the latter half of pregnancy may be avoided or so managed as to avert serious consequences. This care is available to all women, as every practitioner realizes its importance and almost every hospital conducts its prenatal elinic.

Attention directed toward the labor itself has developed many methods for the relief of pain, and procedures in delivery which leave the patient in much better physical condition. And also, after the first two weeks of the puerperium the patient receives, while at the hospital, the most

approved scientific care.

Notwithstanding the greatly improved management of the prenatal period, labor, and the two weeks immediately post partum, there is a most surprising neglect of the remaining part of the puerperium. The puerperium is usually interpreted as the two-week period immediately following delivery. As a matter of fact, however, the puerperium extends over a period of approximately eight weeks. The return to normal of the generative organs is a gradual process requiring the full eight weeks to bring it about. It would. therefore, appear that following the first two weeks there still remains an important part of the puerperium which demands intelligent care. and lack of it often lays the foundation for the future development of birth canal pathology.

As a result of the incomplete involution of the puerperal period the uterus is still enlarged and its supports relaxed. This will often lead to backache, bearing-down, heaviness in the pelvis. dragging sensations, discharge and weakness, all of which are frequently regarded as necessary accompaniments of elildbearing. If these patients are examined when their symptoms appear, it may be found that the uterns is large, in anterior position, but sagging. With such symptoms, a retroversion is usually suspected which, however, is not found. These symptoms are often not reported to the physician as the patient also regards them as a natural consequence of childbirth. If they are reported, the attending physician, in the absence of retroversion may ignore them. At the end of eight weeks, if the symptoms still persist, he may give them consideration and institute measures for their relief. But, by this time, four to six weeks of the most important part of the puerperium have passed without proper attention. With conscientions prenatal supervision, skillful delivery and most approved hospital care directly following labor, it seems very unreasonable and illogical that the remaining four to six weeks which are so iniportant should be almost entirely neglected.

In recognition of this fact, there has been some attempt by various clinics to correct it by advocating certain procedures to aid involution. Polak, in his clinic, used the "monkey walk," a procedure which requires the patient to walk on "all fours" for a stated period morning and night. This maneuver tends to put the uterus temporarily in the normal position but does not prevent it from again sagging when the patient is

erect. Others have advised the knee-chest position, or lying on the abdomen, both of which, in the same way, are of limited value. These procedures are advised not only during the hospital period but patients are instructed to continue them at home. Unfortunately, however, the patient after returning home, in assuming her household duties usually neglects these exercises and such little value as they may have, is lost. If it is desirable to adopt such measures which are of only temporary benefit, it would appear that any plan by which the interns may be continuously supported is both advisable and logical. This can be accomplished most simply and effectively by the use of the Smith-Hodge type of pessary.

The pessary, unfortunately, is not well understood. Its purpose and mechanism by which it acts are not familiar to many, and this in part accounts for its having fallen, more or less, into disuse. It is usually regarded only as an aid in the treatment of retroversion and this indication is generally accepted. Even in this condition, however, the real value of the pessary is little appreciated although it has been before the profession since its introduction in 1863. In view of this lack of appreciation it is not surprising that it has been neglected for other conditions in

which it has a definite place.

It is true that the pessary is occasionally used at the end of the puerperal period when subinvolution or retroversion is actually present. It is now proposed that the pessary he used during the pnerperium for the relief of symptoms due to relaxation, sub-involution and retroversion. All patients, therefore, should be examined during the third week of the puerperium. Those patients showing evidence of poor involution with a large, sagging, hoggy uterus accompanied by backache and bearing-down, can be treated and relieved by the use of a properly fitting pessary. The selection of the proper size for the individual patient is of the greatest importance. At this time of the puerperium a number three or four narrow Smith-Hodge pessary is inserted and allowed to remain two weeks. This is then replaced by a smaller size to allow for the progressive change of involu-The second pessary is removed at the seventh or eighth week when involution should be complete. While wearing the pessary a simple, cleansing douche is used once daily for obvious reasons. The pessary used in this way is a simple and effective procedure. It acts as a continuons support to the uterus and prevents siib-involution, relaxation and displacements without requiring the cooperation of the patient.

My own experience, for the past two years in the use of the pessary in this manner, has proved most gratifying. It has convinced me of the importance of careful observation during a period which has been almost entirely neglected. The complete relief of symptoms by the use of the

pessary justifies its continued use.

Several objections may be raised to the use of the pessary as a prophylactic measure in the puerperium. First, it may be urged that by its presence it actually retards involution. Second, that it may predispose to infection; and third, that perineal lacerations may make its use undesirable or impossible.

In answer to the first, judgment must naturally be used in selecting the proper size, and good judgment can only come through experience. The birth canal is still relaxed in the third week of the puerperium and one may introduce a pessary which is too large and which may prevent the structures from involuting properly. however, by experience one has acquired skill in selecting a pessary of the proper size so that the uterus is maintained in position, the birth canal is not over-stretched and there should be no interference with involution. To fit properly the pessary should be movable in the vagina, and upon straining, only a small part of the anterior bar should be visible. The patient should be entirely unconscious of its presence.

In answer to the second objection: In the third

week of a normal puerperium, the birth canal is not susceptible to infection. The canal between the vagina and the body of the uterus is now distinct. By the third week, as recently shown by Williams, the endometrium is completely regenerated, which in itself is a natural barrier to infection. If there be temperature indicating a morbid puerperium, the insertion of a pessary is naturally contra-indicated.

In answer to the third objection: Tears of the perineal body either as a result of episiotomy or delivery, are usually well healed by the third week. If the tear has been extensive and healing delayed, the pessary can not be used. The narrower types are more desirable as they avoid overstretching and possible damage.

In conclusion, it is emphasized that the puerperium extends over a period of eight weeks; that, during this time, conditions may exist which result in relaxation, sub-involution, and retroversion; that the resulting symptoms of bearing-down and backache at this time are preventable, or may be relieved and displacements prevented by the prophylactic use of the pessary.

THE PRACTICE OF MEDICINE IN 1950

By H. SHERIDAN BAKETEL, M.D., JERSEY CITY, N. J.

An address before the Ocean Medical Society, Brooklyn, January 16, 1933.

UERY: What will be the status of the practice of medicine in 1950? This portentious question, an answer to which your membership desires, should receive the consideration of a prophet, of the seventh son of a seventh son, or of a gazer into the crystal ball, in the middle of which is said to be writ all that is to transpire in the future.

But may not observation and deduction come to our assistance in reaching a conclusion?

1. Immediately after the beginning of the Great Depression, back in 1929, we found that there was no lack of men eager to make forecasts about returning prosperity.

We heard that prosperity would return in a few weeks. Then the date was postponed a few months. Some of the most prominent men in our country, including the President, made statements which a year or two later came to look rather foolish. Finally, no one could be found who would be willing to prophesy that prosperity would return within our own generation.

We now enter the fourth year of the depression, and face the fact that circumstances will move this way or that, irrespective of the prophecies of man. Therefore, we realize that one can make very few predictions with the confidence that they are accurate.

2. If we retrospectively regard the ages of progress, we discern many great changes which no man could possibly have foreseen, or had they been foreseen, people would not have believed.

But we are also aware that many things have not changed, things which have developed and grown, but which to a large degree remain as they have been for many hundreds of years.

Medicine is one—at least that part of medicine which concerns the spiritual relationship between patient and physician.

3. The desire to serve humanity, which has animated the healer for so many centuries, continues today.

Without it, very many of the great advances in scientific medicine which have distinguished our profession, particularly in the last quarter century, would mean far less, for there would be no one to interpret these progressive steps and apply them in a personal way, and accordingly the public would derive much less benefit from them.

4. We must remember carefully this ambition to serve when we consider what medicine will be like 25 or 50 years hence.

Arguments tending toward a revolution in medicine, no matter how logically they may be

prepared, or how well based on studies of medical care and service must be proved in the long run by human inclimations. Can the desire that has continued for so many centuries, on the part of the ill patient, to have a personal physician mini ster to his needs, be changed comparatively over mght?

5 To answer your question I have set out very brovely to prognosticate what medicine will be lile in 1950, and I have enjoyed permitting my imagination to run riot in observing all kinds of rudical changes, with our present system turned

upside down

All the things that physicians have communicated to me in conversations concerning the tuture of medicine, all that I have ever read, including the report of the Committee on the Costs of Medical Care, with the various newspaper editorials discussing it, came to my mind in review It seemed easy to paint an interesting picture based on all these somewhat wild predictions, and if I dated the picture sufficiently far ahead. I would never be called to account for my forecast, as were the men who made those prosperity predictions back in 1929

However, after deliberate reflection I reached the conclusion that the future could not actually hold such startling changes as some would wish us to believe The principal reason is that we

cannot easily change the nature of men

6 It is a human tendency for the ill potient to desire an humane physicion, who will immister to him in a personal, old-foshioned wov, even though the technique and odvantoges applied may be of the most modern sort

It is also inherent in the physician who is a true healer at heart to do his best under the old type

independent system

Of course, there ore changes ahead

Medical practice cannot remain at a standstill, and certainly when we look back 25 or 50 years. and recall the marked changes and improvements —the use of the automobile to increase the physician's radius of action-the telephone, practically placing him in the same room with his patient many nules away-the assembling of physicians in medical office buildings, with consequent closer cooperation, and a very great saving and con venicnce to the patient—the many improvements in diagnostic and therapeutic apparatus and ngents—and finally, the understanding on the part of the physician that he must, in all logic and fairness apply business principles to the practice of medicine in a reasonable degree-when we con sider all these things we realize that there are cert un to be just as striking changes ahead of us

8 One of the questions you expect me to answer tonight is, Will the general practitioner disappear?

I do not expect to be here 100 years hence and so I am not deliberately playing safe in making a

conservative prediction on this question. I think the general practitioner will be here 500 and 1,000 years from now We may not know him by that name, but his service and his relation to society will be the same

His rewards, let us hope, will be larger part, of course, is largely up to him for as the physician proceeds along a course in which he is already making so much progress discovering his economic problems and devising ways to meet them, he will adopt means to make his own particular kind of service more eagerly sought by the public. He will find that what business calls salesmanship can be applied along rational lines in medicine

We do not have to journey very far to find an illuminating example. I am acquainted with a physician in an adjoining state who, 20 years ago located in a comparatively small town, a dozen miles or so from the county seat. His medical preparation was no better and no poorer than that of thousands of his confreres But he possessed foresight and with it wisdom. He early recognized the necessity of giving to his patients a serv ice court to that which they would obtain if they were to consult a doctor in the county seat determined to do even better Consequently, as time went on, he placed in his office the various instruments of precision which are so necessary to enable one to arrive at a proper diagnosis

He kept abreast of the times in every way a result that young man attracted patients Those nationts and their children form part of his chentele today His office is always crowded assistant and two nurses aid in carrying on, and I do not know a more successful practitioner nor a man who is able to furnish definite service of The doctor makes no a more decided character claims to superior knowledge, but as an humane farseeing, wise and competent practitioner, he has applied to his daily endeavors the very best in the art, science, and economics of medicine

A few years ago we heard much more talk on the subject of specialism than today

Hen, not only the public but even many of the medical profession, seemed to feel that the only

good medical man was a specialist

We were alleged to have reached such a fine point of specialism that a patient who called upon an otologist for the treatment of an abscess in the right nostril was told that he must consult an other specialist, as he confined his efforts solely to the left nostril

There are indications that we are commencing to observe a trend away from specialism, and back to general practice. To be sure there are as yet no statistics to prove this, but it is nevertheless cle ii that such a change is being noted. I have been much interested in the opinion recently expressed by a dealer in surgical instruments and supplies, who has an intimate business acquaint

ance with doctors throughout a wide territory in the Southwest.

He had noticed, he tells us, a very marked diminishment in the public's preference for specialists. This was especially noticeable when listening to the comments of the patients coming to his orthopedic and truss-fitting department.

Some of these people have apparently reached the conclusion that the specialist is too likely to overlook pathological conditions in other parts of the body that may have a bearing upon the ailment with which they are afflicted. Of course we know that this complaint is not often justified. Furthermore we are convinced that every person should constantly be under the general survey of a competent practitioner, but the fact that the patients trouble themselves to reason this out is proof positive that they are giving intelligent thought to the matter.

10. I believe the future will see the general medical man occupying a position of great import.

As medical education is becoming better rounded, and our research work is bringing to us conclusive facts, and with better facilities for undertaking postgraduate work, there is no reason why the general man should remain secondary to the specialist.

He has the one great advantage, which patients are appreciating more than ever—namely, a broad perspective of the patient and the ability to include all parts of the body in his investigation. Not only should his sphere of activity include the majority of ill patients, but the well patient also will in the future require the general practitioner's attention more and more in the form of periodic health examinations.

We realize that certain physicians have outgrown the objections once held toward state medicine, and have concluded that there may be a solution to our difficulties in some such new form of medical service. It is not at all unlikely that by the year 1950, and perchance long before that time, we will have worked out a method to provide medical service for those who are unable or unwilling to pay for the services of a private physician.

In doing this, we will be following in the trail of most of the European countries which have long been utilizing a form of state medicine. When we are ready to consider such a plan, the lessons that these countries are learning will be so well known that, if we proceed slowly and cautiously, we may profit by their earlier mistakes.

11. For example, we shall not commit the error of assuming that physicians desire 100 per cent state medicine.

One hundred per cent state medicine would render the family doctor extinct. It would completely eliminate the personal relationship. The result would be fully as unsatisfactory as the public believes conditions are now, and probably very

much more. What we will have in 1950, instead, is undoubtedly a system of part state medicine and part private medicine, in more or less equal proportions.

That portion of the public now treated gratuitously by physicians, either in their private practices or in clinics, or whom physicians are now called upon to treat without charge as hospital ward cases, and all those patients who are so eager to obtain medical service in one form or another without paying for it—all these patients will be grouped together and cared for by the state, county or municipality. The physicians who care for the indigents will work on salary, while the other members of the medical profession in private practice will be automatically relieved of a very difficult burden.

The economic importance of such a change is decidedly obvious. The private physician can then devote himself exclusively to practice for which he is recompensed, to study and, if he is so inclined, to research work.

I regard the term "state medicine" as a misnomer, and utilize it at this moment only because it seems to be the popular term in lieu of something very much better. My preference is for "public medicine," because doctors working for the Government in any of its forms are really practising "public" medicine in contradistinction to the private practice of medicine, in which they are compensated by the individual, rather than through some form of taxation.

12. The very important point to be emphasized is that we must not permit the pendulum to swing too far in one direction.

There are some phases of public medicine which undoubtedly sound attractive in these days of de-

pression and every-man-for-himself.

However, the fact that we are temporarily experiencing difficulties does not mean that private medicine should disappear, and that all of us should shift to a government payroll. If we as physicians are to take an active interest in the coming developments of medical practice, and are to guide our political leaders, as well as the philanthropists, in putting changes into effect, we must advocate that this metamorphosis be effected conservatively. We must not ourselves, nor allow the others, to make us leap out of our present pool into a new one, the depth of which we know not.

13 This brings us to the question: "Who will, in 1950, be the private practitioners, and who the state's doctors?"

We know that there are men in the medical profession who are extremely well adapted to conditions of private practice. They possess every qualification to make the most successful types of private practitioners, either general or specialist.

There are, on the other hand, men who are scientifically quite as capable, but who for one rea-

son or another could employ their ability more effectively under salaried conditions. Then there are many between these two extremes, but it is very clear that we have one distinct class in the profession which could never be happy under anything but the private form of medicine, and another portion which could work very happily under governmental supervision.

14. Since we have these two graups, and two corresponding kinds of patients—it remains for the future to enact an odjustment. I believe it

will be un fait accompli by 1950.

15. Another question that is causing speculatian is the development of the private group clinic.

There are approximately 150 group clinics in the United States, whose staffs range from three or four, to thirty or forty men. Then there are very many medical partnerships, which are actually groups in the making, as a partnership often attracts a third and sometimes a fourth member until a full-fledged group evolves.

The majority of the groups are scattered through the Middle West, with particular concentration in Minnesota, Wisconsin, and Iowa. There are a considerable number on the West coast, some in the South, and a few have been developed

in the East.

Discussion among physicians, economists, and public health authorities would doubtless reach the conclusion that the group idea is due to spread rapidly and perhaps that eventually the largest part of private medical service will be so provided.

16. I have studied this question at close hand recently, and have come to the conclusion that here again we are running to extremes, and ex-

aggerating the future trend.

It would seem after all that we will have no such development as is frequently predicted, on the part of the private group clinic, though there is no question that under certain circumstances, in the right location, and under efficient management, the group clinic fills a decided need, and can serve a most useful purpose.

We are familiar with the arguments concerning the greater economy offered by the group—the fact that with one overhead, a mutually shared equipment, and subsidiary personnel—there can be some real saving in providing medical service, which saving can be passed on to the patient. It is claimed by some that in this form we have a final solution of the problem of the costs of medical care.

The group idea is excellent, but I seriously doubt that it will spread much more widely than at present, and particularly am I hesitant to believe that it offers any conclusive answer to the medical cost problem.

The outstanding reason for this belief is that only a certain proportion of cases can be most successfully handled in the group clinic. By that I mean the complicated cases which the general

practitioner must turn over for more thorough examination and diagnosis to some competent specialists. In addition to these cases, there are a certain number of patients who will go directly to the clinic for any sort of trouble, no matter how minor. These patients seem to be attracted either by the novelty of the clinic, or by the belief that they will get superior service at lower prices. Some of these patients appear to regard the general practitioner as a rather old-fashioned, somewhat incompetent type of individual, to be called only at three o'clock in the morning, to treat a pain in the epigastrium. But will the rank and file consult a group, instead of their own physician?

17. In certain cammunities, the group clinic con offer very warked advantages, both to the public

and to the physicious.

I know of a smallish city in Maryland where a group of specialists got together, took over what had been the Odd Fellows' Hall, and changed into an efficient professional building. In all there were about a dozen men in the group, and the specialists did all their work either in the building or in the nearby general hospital, allowing all the house calls to be handled by two general practitioners, who were partners in the group.

One excellent service offered by this organization was a complete and very thorough examination in which each of the specialists, when necessary, took part, the whole occupying but a few hours of the patient's time. The charge was \$25, which was pro-rated among the various members of the group according to the time employed by

each.

However, we need to understand that there are many factors which can interfere with the smooth working of such an arrangement, even such factors as the difficulty of cooperation between the doctors themselves, not an infrequent occurrence.

It seems to be almost axiomatic that a group clinic, in order to be really successful, must be headed by one dominant member as its chief, who surrounds himself with men who are professionally and scientifically competent, but who are not prone to place self-interest above the interest of the group as a whole. The germ of professional jealousy is one of the greatest hazards to the duration of the group clinic.

18. In 1950 I should expect to see many group clinics answering this description, but I doubt if the number will be largely in excess of those now in existence.

We will doubtless have a considerable number more than today due to the growth in population, and the building up of communities which are not large enough now to support such groups. But that would be simply a normal development, and it would not mean that the group idea had spread very rapidly beyond its present bounds.

As a matter of fact, some close observers feel

vas struck by the vigor of his stride, the inforce he seemed to possess and his all-round iness. He was obviously a Norseman but ughly Americanized in his bearing. I catad him as a successful business man in the , yet there was a something which hardly

someone ... in with the picture of the business man. Before we passed the Banks he introduced himself. He was a Scandinavian, and a physician, lad be her brought fad be her brought fad be her brought was merica when a year old, had grown up in ruinment diwest and graduated from one of the best is some tell suin hools. This man was an artist craftswish suing on didicine was his art and his craft. At which said said slicine was his art and me coungster is dained by the stell full of the fire of the youngster is dained by the stell full of the fire calling. He had is claimed by some is still full of the ure or the final solution of its discovered his true calling. He had final solution of the life far West after serving his interne-cal care.

The group idea is I cared for the ailments of a widedock that it will speciation. He assured me that while at present and spredation. He assured the earth. here that it and springers, they were the salt of the earth. here that it offers any going abroad to study, not to spended on the same of t medical cost problem.

cialize, merely to continue his study of general medicine, and then instead of going to some nearby city, after his return from Europe, he was going back to his own people in his little town, because he felt that those people were entitled to the very best which medicine could give. "Those people stood by me," he said, "when I needed their money, and now I shall show my appreciation by giving them whatever added skill may come to me through broader knowledge."

This man exemplifies the spirit of craftsmanship which is so observable in your profession and Craft, art, patience are of first impormine. tance! Where can you look and not see physicians who are putting aside the hope for great emolument in order to serve those whom they term as "their people." Those men are rich in those things which constitute the very best in life. They are heroes who die, unheralded and unsung, without worldwide honor, but not without the very deep and sincere kind of thanks of those whom they have served. And with such practical physicians as these the medical profession is replete.

24. It is absalutely necessary for us not only to recognize our croftsmanship, but to embellish

We should draw a more distinct line between medicine practiced as a craft and that practiced as an industry, so that the public will be attracted by the first type. Our course must be, as 1 have endeavored to demonstrate, to make the private medical man attractive to the public. No one suggests municipal movie companies or municipal movie honses. That is because private industry provides the type of craftsmanship which makes motion pictures attractive to those of the public who enjoy them.

25. Let us hope that by the year 1950 we, as a profession, will have mastered this new art af presenting our croftsmanship in the best light.

26. On the whole, and considering all the factors discussed, I think the pasition of the medical profession of 1950 will be much more favorable. and the lot of the average physician will be much happier than today.

We are now going through a period of transition, as indeed is the entire world. We are learning the comparatively new science of economies. and are applying it to our problems. When we emerge from this period, we will find medicine essentially as it was before. Human nature changes but little in the course of the centuries.

The surface aspects of medical practice in the future will be different, doubtless along the lines suggested, but the changes will not be nearly as extreme as some feel.

Then, as now, we will stand and serve.

The outstanding rea only a certain proportion successfully handled in t I mean the complicated

MEDICAL SURVEYS

Three books of reports of Medical surveys that directly affect the physicians of New York State have been issued within a little over a year:

- 1. Report of the Governor's Health Commission of New York State.
- 2. Report of the National Committee on the Costs of Medical Care.
- 3. Report of the Commission of the Association of Medical Colleges on Medical Education.

Each volume considers three questions which are of vital interest to both the medical profession and the public:

1. The medical needs of the people;

- The extent to which the present system of the practice of medicine supplies those needs;
- Recommendations for changes in medical practice and administration so as to meet the health needs of the people.

Medical service cannot be considered alone, but it is interrelated with other basic needs of a community. Every person is subject to at least three basic conditions which affect his counfort and satisfaction. This trinity of conditions which are present in his mind daily and even hourly are:

- 1. Social status, or those conditions arising from his contact with his fellows;
- 2. Wealth, or his financial and economic status;
- 3. Health, or his physical condition.

The physician is concerned with health, and is insistent on the recognition of his leadership in that field for which he is specially trained. But the maintenance or correction of health conditions has an intimate connection with economic and social conditions; and these are fields in which the physician is not the leader. Economic and social conditions are the peculiar fields of government officials, churches, schools, business companies and social organizations. These leaders will not accept the domination of even the health segment of their field by doctors, any more than physicians will accept the domination of the business men in their own peculiar field of medicine. The administrative contact of the physician with other persons or organizations must be by conference and advice rather than by law and compulsion. When doctors sit down with officeholders and social workers, and discuss the medical phases of their economic and social work. both parties are usually able to reach satisfactory agreements.

Each of the three reports to which reference is made at the beginning of this editorial deals with medical service from the standpoint of either economics or social science. All agree that medical service must be given by a trained physician. It is only natural that office holders and business

men should assume that they can hire physicians to deliver the services on order from a central office; and that the people will accept those services on the sole ground of efficiency. It is also only natural that physicians should emphasize the value and necessity of the friendly contact of the individual doctor with the individual patient.

The major recommendation of the Governor's Health Commission was the establishment of official County Health Departments. While legislative bills for the compulsory establishment of the County Units have been proposed, their voluntary formation under the present law is still in force, and under it the Columbia County Medical Society has followed the example of Cortland and Sutfolk in advocating and securing the county-wide administration in public health. These three counties have shown the way by which the medical profession may reach agreements with governmental officials in health matters.

The report of the Committee on the Costs of Medical Care contains proposals for introducing the commercial methods of large business corporations into the distribution of medical services upon a large, impersonal scale. Physicians are now in a position to discuss the plans of the Committee, and to make intelligent suggestions for meeting the medical aspects of economic conditions which statisticians and business men seek to correct in their own way.

The report of the Commission on Medical Education is the official pronouncement of the Association of American Medical Colleges on the subject of the education of practitioners of medicine. It conforms to the opinions and attitude of practitioners of medicine more closely than do the two other reports; but yet the influence of the medical societies will be needed in carrying out its recommendations.

The leaders of the official organizations of physicians will give deep thought to the recommendations of the three committees, and will doubtless develop plans of cooperation which will be acceptable to the medical profession and to representatives of economic and social interests.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Group Meetings:—This Journal of February, 1908, contains two propositions for group meetings of the Medical Society of the State of New York in addition to the annual neeting and of those of the District Branches.

The first proposal was made by a special cominitie on annual meetings to the effect that the State Society hold a semi-annual meeting, under the auspices of four groups of District Branches. Each group shall sponsor a meeting and its program, one year in four. This plan was discussed in the House of Delegates, but no decision was reached.

The second plan was proposed by the American Medical Association that seven Branches be formed; that the North Atlantic Branch consist of the New England States, New York and New Jersey; and that a meeting be held in each once a year.

This plan was rejected by the House of Delegates on the ground that there are already a sufficient number of medical societies.

MEDICAL PROGRESS

Pock Diseases.—Enriques Paschen describes the so-called elementary bodies, discovered by Borrel in fowl-pox and sheep-pox and by himself in variola vaccine. These organisms are identical morphologically and culturally. They can be regularly demonstrated in cow-pox lymph, rabbit virus lymph and variola pustules. Proof that these bodies are the causative agents of pock diseases has been given by their morphological demonstration in the tissue cultures and vaccine culture in a medium free from cells. Vaccination with cultures from an infant lymph always produces the same type of reaction as the usual calf lymph. Starting from a common source the original pock (probably a human pock), by continuous passage through the same species of animal, developed three different strains, namely, human pox, fowl-pox and sheep-pox. In the transformation of human variola through the cow or horse into vaccinia, it is highly probable that the pock agent finds its way into the mucous membrane of the upper respiratory organs and sets up a thrombophlebitic process in the lungs with enormous increase of the Otherwise there is no explanation for the sudden and enormous inundation of the blood stream and for the occurrence of metastases in the skin and internal organs. Experimental work with neurolapine (neurovirus in rabbits) entirely supports this hypothesis. With vaccinia the agent circulates regularly in the blood, but there is only a bacteremia and we have a minus variant which can be removed, at least partially, by forcing vaccinia virus to accustom itself to a tissue which is strange to it. This neurovaccine is very similar to variola, its characteristics being the formation of metastases and the liability to necroses and hemorrhages. Vaccinia has an affinity not only for cells and tissues of epablastic origin, as has been thought by some investigators, but also for mesenchymal tissue. It seems that the socalled affinities are merely the result of acclimatization to a new environment. All investigators have found virulent small-pox complicated by the presence of pyogenic cocci and have supposed that the difference between alastrim and small-pox consists in the former being due to the pox virus alone, the latter to the pox virus combined with pyogenic cocci. The comparison is not quite adequate inasmuch as neurolapine regularly kills the rabbit without the cooperation of bacteria. Vaccinia attacks the cells of the three germinal layers. while fowl-pox attacks only ectodermal and

(to a less degree) entodermal epithelium. The inclusion bodies have without exception a lipoid component, which is never found in vaccine. The pustule produced by vaccinia on the skin or comb of the chick does not show the histological features of fowl-pox, but those of vaccinia or variola, without the formation of Guarnieri bodies. These the author claims are masses of Paschen bodies. Recent experiments show that variola is transformed into fowl-pox by insect vectors, such as Culex pipiens—British Medical Journal, November 26, 1932, ii, 3751.

Tissue Changes in Virus Diseases.--J. C. G. Ledingham, writing in the British Medical Journal, November 26, 1932, ii, 3751, shows that the types of tissue change met with in various virus infections do not differ in essence from those encountered in infections due to visible bacteria. Where they seem to differ, as in virus diseases associated with characteristic cell inclusions, the difference is probably not really of a fundamental nature, or one bearing the implication that viruses are essentially intracellular parasites. It is more probable that the penetration of epithelial cells which takes place in fowl-pox and vaccinia is an accidental occurrence. In the great group of pock diseases, including mammalian and avian pox, the essential lesions are in the skin, with only occasional evidence of gross changes in organs, but in the skin itself there are notable differences in the mode of attack and development of the lesions. In vaccinia and small-pox the skin lesion is essentially an inflammatory one. It is, however, well recognized that ordinary vaccination may be followed by definite splenomegaly, and in fatal cases of small-pox focal necroses in the liver have been observed. Yellow fever affords an example of a virus disease which apparently produces a pure necrosis of parenchymatous cells without any inflammatory change. The lesions consist essentially of fatty degenerations, necroses and necrobioses affecting liver, kidney, heart and spleen, with little or no trace of inflammatory response, except possibly in jaundiced conditions. Lesions of the nervous system fall into two classes: (a) those represented by herpes and vaccinia—the latter after cerebral inoculation only-which produce meningitis with little or no encephalitis, and (b) those represented by rabies, poliomyelitis, Borna disease and louping-ill, which attack mainly the neurons. The latter group also contains the postinfectional and post-viral encephalomyelitic

conditions which are accompanied by extensive demyelination. Pulmonary manifestations of virus diseases, such as are probably contracted by the respiratory route, are seen in psittacosis and influenza. In psittacosis the manifestations are essentially lobar, accompanied by fibrous exudate and hemorrhages in In virus diseases severely damaged areas. such as distemper, rinderpest, fowl plague, etc., there is a lack of obvious change in fatal cases. The outstanding example of proliferative lesions is seen in Rous sarcoma and those avian types which are capable of being induced by cell-free material. These seem to be gennine malignant neoplasms. Russell's finding of intranuclear bodies similar to Paschen bodies in 33 per cent of gliomatous tumors points to a virus as being the cause of these growths. It has become increasingly evident that a change of host or a change in the method of propagation of a virus in experimental work may profoundly alter the pathological picture and bring to light unexpected tissue affinities. Thus the virus of vaccinia, after serial propagation in the rabbit, acquires greatly enhanced power of propagation from whatever site it is introduced. It has also been shown that concomitant bacteria may participate in tissue changes ostensibly due to virus.

Is Disinfection Useful in the Campaign Against Contagious Diseases?—The view is taken by A. Roeliaix in the Journal de Médecine de Lyon of December 5, 1932, that disinfection, even when carried out meticulously, is in reality nothing more than an accessory prophylaetic measure, and that in certain affections it is entirely useless. It is the patient himself who is a source of danger, with his fresh secretions and excretions, and not the microbes which he cast off during the days or weeks just past, for in the majority of the contagious diseases these survive but the briefest time after they leave him, and are of such fragility that they disappear, as it were, as soon as they fall off into his environment. Such is the case with measles, epidemic cerebrospinal meningitis, rubella, acute anterior poliomyelitis, whooping cough, grip, and mumps. Likewise, in diseases transmitted exclusively by insects or rodents, such as yellow fever, malaria, encephalitis lethargica, typhus exanthematicus, etc., disinfection is completely useless. Here it is the intermediary carrier that must be got rid of. The only diseases calling for complete disinfection are smallpox, scarlet fever, diphtheria and tuberculosis, and even in these the importance of such measures should not be exaggerated. In most cases it is direct contagion from the patient himself that is responsible for the spread of a disease. fact is too often forgotten in the zeal with

which disinfecting measures are undertaken upon furniture, walls, clothing, etc. A child sent to the country contracts scarlet fever; he is removed and the whole premises are disinfeeted. A month later another child is sent to the same house; he comes down with scarlet fever; the blame is placed on the inadequate disinfection of the place, while in all probability it was the woman of the house who was a carrier, the disinfection of whose throat would have been more useful than that of the premises. It is the same with puerperal fever in maternity hospitals, where the streptococcus is at home in the throats of the personnel. from which it continually produces new infections. Examples might be multiplied ad in-Disinfection should be relegated to finitum. a secondary place among means of prophylaxis. To assign to it an excessive importance is to give a false sense of security and to divert the attention from more appropriate prophylactic measures which would be effective if applied in its stead.

Tobacco Smoking.-The question whether a brand of cigar or cigarette is to be rated a "inild" or "strong" depends chiefly, says Friedrich Müller, on the amount of its nicotine content. Thus a strong Virginia eigar contains an average of 3.5 per cent of nicotine, with various other kinds ranging from 2 to 5 per cent, while cigarettes vary from the relatively weak nicotine content of oriental tobacco (0.8-1.2 per cent) to the heavier content of the French product (2-3.5 per cent) or the American and English (1.1-2.9 per cent). The amount of nicotine content has been proved to have nothing to do with the color of the tobacco leaves. It is the aim of scientifically conducted manufacturing concerns to produce eigars and eigarettes with a fine aroma, which at the same time have a nicotine content that is not too high and that remains uniform. Since the amount of nicotine demonstrated in tobacco leaves would lead one to expect a much higher toxic effect than is actually discoverable in smokers, there has been reason to . suspect that only part of the nicotine contained in the leaves passes over into smoke and produces its characteristic effect, and that the rest is destroyed in the burning eigar as it passes into the air. It has been established experimentally that only about one-quarter of the nicotine passes into the mouth (30 per cent with eigars, 20 per cent with eigarettes), and that of the nicotine drawn into the month about two-thirds is again puffed out from the mouth into the air. If, however, the smoke is inhaled into the lungs, 5 to 7 times as much nicotine becomes effective in the body as is the ease with simple mouth smoking. Furthermore the nicotine in the second half of a

cigar is more available to the smoker than that in the butt of the cigarette. Since it is thus established that it is the individual mode of smoking that determines the amount of nicotime that becomes effective, all that remains is to make a quantitative determination of the amount of nicotine actually absorbed, which can be done very quickly by examining the urine. Many attempts have been made to solve the problem of manufacturing tobacco poor in nicotine. It is easy to soak out the nicotine content from the leaves, but so much of the aroma is lost in the process that no satisfactory products can be made from them. Austrian Board of Tobacco Control, however, by heating them to a given temperature, has succeeded in freeing them from their salts. which pass off in superheated steam. suitable care the nicotine content can be reduced to 0.5 per cent, and be maintained constant at this limit. From a medical point of view these tobacco products can be designated as harmless, but it remains to be seen whether they suit the taste of the smoking public. A number of other processes have been tried. such as that of binding the nicotine in the smoke, but have proved to be entirely useless when submitted to an exact test.-Münchener medizinische Wochenschrift, November 18, 1932.

A Million Volts Against Cancer.—Among the many sensational news items in recent times, says H. Holthusen, writing in the Deutsche medizinische Wochenschrift of December 2, 1932, was the announcement that the splitting of the atom, already achieved in the physical laboratory, had opened the way to the medical use of high voltage electricity, and that through such an increase of the energy of the individual process as had been made possible by the million-volt tensions the therapeutic effect of the rays had been cor-respondingly increased. This is a misunderstanding. It must not be overlooked that between the problem of splitting of the atom and the effect of rays upon cells fundamental differences exist, despite a certain internal relationship. They are related, in so far as the rays here too serve in the end to loosen the structure of the cell molecule and to "denature" it, whereupon the cell, in the event that it has received a sufficient amount of bombardment, will perish. But the decisive difference consists in the amount of the energy masses available for the individual elemental process. A clear distinction must be made between, on the one hand, the amount of the individual quantum corresponding to the energy which is available in the individual process, and which determines the quality-in absorption-and, on the other hand, the total energy of all the quanlums, through which the intensity of the ir-

radiation is determined. Now it happens that in roentgen rays of all qualities and in the gamma rays the elemental energies which become free after absorption of the rays are fully sufficient to introduce reactions of which the irradiation-degeneration of the cells is to be regarded as a secondary result. Hence one cannot expect a fundamental increase of therapeutic efficiency from an increase of elemental energies such as is produced by increasing the tension generated. The attempt to draw conclusions as to therapeutic possibilities from the extraordinary physical effects of rays generated on a million-volt apparatus is not well founded. Such an announcement in the daily press under sensational headlines can only produce an erroneous impression in the present stage of investigation, and is all the less justified in view of the lack of technical equipment presupposed for the practical accomplishment of therapeutic irradiations. The problem of cancer control with radiant energy lies today in the field of divided dosage measured on a time basis. What is needed is to determine for each carcinoma the most favorable conditions of distributing the dosage of rays, in terms of time.

The Vascular Tonus of the Lower Extremity after Lumbar Sympathectomy, Studied with the Aid of the Adrenalin Reaction.—A report is made by D. Danielopolu, A. Aslan and I. Marcou of studies with reference to the effect of lumbar sympathectomy upon the lower evtremities, following an earlier study (1926) of the effect produced upon the vasomotors of the left upper extremity by excision of the stellate ganglion. The authors conclude from their two series of researches that the vessels possess an automatism of their own which allows them to contract and dilate. When, however, a vessel is separated from its centers, the variation of its caliber, due to this automatism. is completely disequilibrated. Normal vasomotor oscillations are due to the fact that every vasoconstrictor movement calls into action a vasodilatation, and vice versa. The authors think that this regulatory mechanism is reflex, with a centripetal and a centrifugal tract. The vessels of a sympathectomized limb present two important modifications, namely. hypotonia and exaggeration of their automatism-phenomena due to interruption of the centrifugal or the centripetal tract, or of both these. Practically, the hypotonia represents an improvement in the circulation of the limb; but, on the other hand, the exaggeration of automatism predisposes the vessels of the limb to crises of vasoconstriction which are more energetic and more prolonged than in a normal limb, and which cannot but diminish the nutrition of the limb. But the clinical results show that after sympathectomy the trophic phenomena disappear, and that intermittent claudication improves or disappears, which proves that despite the energetic crises of vasoconstriction to which a sympathectomized limb may be subjected, the circulation of the limb is clearly improved. Sympathectomy is. therefore, a very useful operation in arterial obliteration in the limbs. The authors experi mental studies have demonstrated that the most important region, the one which it would be most logical, physiologically, to intercept in cases of obliterating arteritis of the lower limbs, is located at the promontory Physio logically an interlumbosacral sympathectomy including this region would be the most logical operation in this condition, and also in certain affections of other organs which receive their mnervation through these ganglions. The idea is based only on physiological research in the dog, and requires the confirmation of general surgical practice-Bulletin de l'Académie de Médecine de Paris, December 6, 1932

Stenosis of the Larynx and Glycosuria in Children -It has long been recognized, says Martin Strumpel, writing in the Deutsche medizimsche Wochenschrift of October 28, 1932, that diabetes mellitus may produce changes in the larvin. In this connection a case of the author's In this case a boy of 8 years. is of interest previously healthy, suddenly developed within the span of 6 hours a serious air hunger, with a loud laryngeal stridor, in which inhalations produced only transitory relief The laryngoscope reverled masses of mucous accumulations after removal of which the eniglottis, arytenoid region and vocal cords were all seen to be greatly reddened and swollen from inflammation ing the examination the urine was analyzed and found to contain a trace of albumin, and to be sugar positive (16 per cent) as well as positive for acetone and acetic acid. Intubation improved the breathing and caused the cyanosis to dis As it was evident however, that the child's affection was no transitory condition, a tracheotomy was performed, after which the res-piration was entirely free. The glycosuria was treated at once by administering daily 570 calo ries of food with 3 x 5 units of insulin. By the 9th day the laryngeal findings were negative and the cannula was removed, the insulin was stopped at the same time, on the 14th day the urine was normal and the boy was discharged cured. In judging this case 2 questions arise. (1) Was this an instance of diabetes mellitus which crused the changes in the larvnx, or (2) was it a gen eral infection which brought a glycosuria in its wake? The first view can not be upheld in view of the total absence of all other symptoms and sometic findings of diabetes mellitus. It seemed more reasonable to adopt the second view, and

this was also supported by the negative results of examination 5 months later, when the urine and blood sugar pictures were still found com pletch normal. Whether this was a case of injury to the kidues or of one to the panereas is difficult to determine The positive albumin test upon admission nuglit point to a lesion of the kidnes. On the other hand the prompt response to insulin and a carbolisdrate dict are against this view, since such response is not the rule in so called renal diabetes. It is therefore more reasonable to suppose that the cause of the illness by in an injury to the pancreas. That the in fectious attack makes itself felt at the same time in the mucous membrane of the larvax in the form of a severe swelling is a rare circumstance hardly to be found in the literature

The Beneficial Effect of Fatty Alimentation in States of Cachexia -The attention of M I Maignon was drawn to the rapidity with which protein denutration was arrested in diabetics in the cachectic stage by substitution of fats for glucides in the diet. The question arose whether fats do not intervene in protein metabolism by exerting a favorable action on the utilization of proteins, so that the latter do not simply supply energy but also serve as modifiers of the quality of nutrition, somewhat after the manner of vita-Maignon's experiments on white rats in 1918 had already shown that rations of ovalbumin-fat permitted longer survivals and longer perinds of fixity of weight than rations of oval bunun-glucide Repeating these experiments in 1928-1931 and adding vitamins A and B, he found the same advantage in favor of fats with regard to the utilization of proteins. His latest studies have led to the conclusion that with ra tions containing a medium quantity of protein the balance sheet is practically the same in the two cases but where the ration contains a large amount of protein there is a marked advantage in favor of fits. If the fact is taken into consideration that with ovalbumin-fat the destruction of an additional portion of protein occurs in view of the production of the minimum of car bohydrates necessary, which the fats are incapable of furnishing, we are forced to the conclusion that the balance sheet would always be better with ovalbumin glucide rations, in which this additional destruction does not take place. The fact that we find with fat a balance sheet equivalent and even better for rations very rich in proteins can be explained only by a better utilization of proteins when associated with fats by virtue of proteosynthesis. This view that fats serve as qualitative modifiers of nutrition has recently been confirmed by the work of Americans establishing the fact that fats exert an effect upon growth and that they also have a true sparing action -Bulleun de l'Académie de Médecine, November 15 1932

LEGAL

INSANITY AS A DEFENSE IN CRIMINAL CASES

By LORENZ J. BROSNAN, ESQ. Counsel, Medical Society of the State of New York.

It has for years been the rule that an act done by an insane person is not a crime and as a result in many notable cases of homicide insanity in one form or another has been availed of by the accused as the theory of his defense. In certain recent cases an attempt has been made to extend the defense so as to cover cases where the defendant is able to prove that he was of subnormal mentality. The courts have uniformly been cautious in their dealings with defenses of this character.

A recent first degree murder case which arose in a Western State shows the manner in which the courts handle such a defense. In that case the defendant sought to establish as a defense that although he was an adult he possessed only the intelligence of a child of from seven to nine years of age. The testimony showed that the defendant had in eight years of schooling never progressed further than the third grade; that subsequent to a kick in the head by a horse at the age of ten he had shown an almost complete lack of intelligence. Various of his relatives stated that they were of the opinion that the prisoner was insane. The court in affirming a conviction on the grounds that nothing in the testimony was sufficient to support the defense of insanity stated in part:

"But an adult with the intelligence of a child from 7 to 9 years of age would be mentally capable of committing a crime unless it were shown by a preponderance of the evidence that such person were insane under the tests laid down by the court ***. In other words where an adult person has the intelligence of a child from 7 to 9 years of age, that fact alone cannot be made the test as to whether he is insane and therefore not capable of committing a crime under the rules and tests announced by the court **."

In another similar situation that recently came up in New England, the defense sought to establish that the accused was "just above the feeble minded level" and of the mental age of about twelve years and that he was therefore not responsible for his criminal acts. The court in its opinion said:

"Criminal responsibility does not depend upon the mental age of the defendant nor upon the question whether the mind of the prisoner is above or below that of the ideal or of the average or of the normal man, but upon the question whether the defendant knows the difference between right and wrong, can understand the relation which he bears to others and which others bear to him, and has knowledge of the nature of his act so as to be able to perceive its true character and consequences to himself and to others."

As another court stated it the general rule seems to be substantially as follows:

"A subnormal mentality is not a defense, to a charge of crime unless the accused is by reason thereof unable to distinguish between right and wrong with respect to the particular act in question."

The said decisions seem to be in accord with the rule followed in this State. Our Penal Law contains a provision which specifically limits the defenses of insanity that may be interposed. Said section (1120) provides in part as follows:

"A person is not excused from criminal liability as an idiot, imbecile, lunatic, or insane person, except upon proof that, at the time of committing the alleged criminal act, he was laboring under such a defect of reason as:

"1. Not to know the nature and quality of the act he was doing; or,

"2. Not to know that the act was wrong."

Under the said provision it has been repeatedly held that the type of insanity that can be available as a defense in a criminal proceeding is the type that produces in the sufferer such a state of mind that when he commits the act, he does not know that it is unlawful and morally wrong, Evidence tending to show mere pecularities therefore has been ruled to be no evidence of insanity. Attempts have been made under the said provision of the law to obtain an interpretation of the law so as to excuse the type of "defect of reason" that was claimed to lead the accused to commit the acts believing in his own mind that he was right. An example of the said sort of case was one that arose some twenty years ago in which a defendant had admittedly shot and killed his mother. The insanity defense consisted of proof that his mother had for years before the killing neglected him, and he felt that he was not doing wrong in "removing" her as the person who had been responsible for his unfortunate condition in life. There was a failure to support the claimed insanity by any proof that the defendant was suffering from any such disease. The court in affirming a conviction stated the following in its opinion;

"No matter how firmly the defendant may have been convinced that it was not wrong for him to kill his mother, his convictions to that effect could avail nothing as a defense unless they were the outcome of mental derangement * * * a person is not excused from criminal liability as an insane person except upon proof that at the time of committing the alleged criminal act he was laboring under a defect of reason which, furthermore, must have been such as to render him either (1) ignorant of the nature and quality of the act he was doing, or (2) ignorant that the act was wrong * * * The phrase 'defect of reason' in the statute means disease of the mind, and a person who has committed an act otherwise unquestionably criminal may not be relieved from the consequences of that act where insanity is relied upon as the sole defense, unless at the time of the commission of the act he was suffering from some disease of the mind?

Another similar case involved the defense of insanity supported by the story that the defendant had heard the voice of God calling upon him to kill the victim as a sacrifice and atonement and that he had felt therefore that he was justified in taking life. In that case the accused was held to answer to the law if he knew the act was wrong in the sense that it was forbidden by law, regardless of his delusion

In some jurisdictions a rule has been adopted giving an interpretation to the instinty defense to include cases of so called "irresistable impulse" Such cases are cases where the defendant although he knows that the act he commits is wrong, does the act under some insane delusion which prevents him from choosing between right and wrong The law in this State, however, does not accept the said doctrine. It is expressly dealt with by Section 34 of the Penal Law which reads as follows

"A morbid propensity to commit prohibited acts, existing in the mind of a person who is not shown to have been incapable of knowing the wrongfulness of such acts, forms no defense to a prosecution therefor"

The propriety of the New York rule can well be appreciated in the light of the following state ment made by the Court of Appeals in one of the

leading cases on the subject

"We are asked in this case to introduce a new element into the rule of criminal responsibility in cases of alleged insanity, and to hold that the power of choosing right from wrong is as essen tial to legal responsibility as the capacity of dis tinguishing between them, and that the absence of the former is consistent with the presence of the latter. The argument proceeds upon the theory that there is a form of instinity in which the faculties are so disordered and deranged that a m in, though he perceives the moral quality of his acts, is unable to control them, and is urged by some mysterious pressure to the commission of acts, the consequences of which he inticipates but cannot avoid

"Whatever medical or scientific authority there may be for this view, it has not been accepted by courts of law. The vagueness and uncertainty of the inquiry which would be opened, and the manifest danger of introducing the limitation claimed into the rule of responsibility, in cases of crime, may well cluse courts to pause before assenting Indulgence in evil passions weakens the restraining power of the will and conscience, and the rule suggested would be the cover for the commission of crime and its justification doctrine that a criminal act may be excused upon the notion of an irresistible impulse to commit it, where the offender has the ability to discover his legal and moral duty in respect to it, has no place in the law"

The possibilities of unjust results from these general rules may at once be suggested, but the wisdom of these rules can hardly be questioned The courts too frequently encounter faked defenses of insamity, and must be equipped with harsh remedies to apply when required juries are in the final analysis the triers of the facts, and, it is safe to say, very few truly instine persons are impustly caused to suffer for crimes committed by reason of their insanity

ALLEGED NEGLIGENT OPERATION FOR HEMORRHOID

\ doctor specializing in surgery was consulted by a middle aged man, who stated to the doctor that he was suffering from a hemorrhoid and that he wished the doctor to operate upon him im-

The doctor put him in a saintarium prepared lum for the operation by enem is and shaving, and the same afternoon sent him to the operating room Examination had shown that one large hemorrhoid protruded from the right side of the anus and that two smaller hemorrhouls were also present The patient however, requested the doctor to simply remove the largest one

The doctor undertook the operation under local anasthesia injecting the area with one per cent novocame The patient however, was too nervous and musted that he be given a general an esthetic, so consequently he was put under a gas oxygen ether anæsthetic The doctor stretched the anal sphincter enough to turn out the hemorrhoid, applying an electrical hemorrhoidal clamp consisting of two jaws that seized the hemorrhoid and clasped it tightly, after which electric current was turned on to coagulate and cauterize the tissues between the jaws of the clamp. The protruding hemorrhoidal tissue was then removed by an electric knife. There was no bleeding during the operation and the patient was returned to his room in excellent condition. As soon as he recovered consciousness from the anæsthetic, the patient told the doctor that he wanted to go home. The doctor, of course, insisted upon his remaining in the sanitarium. The day after the operation the doctor was no longer able to restrain the patient from his intention to leave the sanitarium. quently he was discharged on that day against the doctor's wishes. It apeared that he drove in an automobile twelve miles to his home. The doctor never saw him again.

Thereafter, a suit was instituted against the doctor in which the patient claimed that the doctor was guilty of malpractice in that he had used an improper technique in performing the operation. The plaintiff's complaint claimed that the proper performance of the

operation required the clamping of the hemorrhoid and the severing thereof with a hot instrument and that the operation would have been bloodless and non-injurious if it had been so performed. The plaintiff further claimed that the defendant in the operation negligently tore and destroyed a portion of the sound membrane of plaintiff's rectum and that as a result he was caused to bleed profusely and to suffer great pain and agony; that the functions of his rectum were greatly impaired and that he was compelled to undergo a second operation to correct the condition alleged to have been caused by the defendant.

After the action had been noticed for trial it appeared upon the calendar several terms at which times the attorneys for the plaintiff showed no particular inclination to try the case. The attorney for the defendant communicated with the plaintiff's attorneys in an attempt to force the matter on for trial and dispose of it. Plaintiff's attorneys then appeared in court and told the judge that they had withdrawn from the case. The case was called for trial and no one appeared to represent the plaintiff. A judgment of dismissal was thereupon entered in favor of the doctor.

CLAIMED NEGLIGENCE IN OPERATION ON EYE-SOCKET

A patient was referred by a general practitioner to the defendant in this case. who specialized in the treatment of diseases of the cyc. He received a history that the patient had in some manner fainted when near a stove and falling on the stove burned her right eye. Examination showed that the eye-ball had been badly burned and that there was no way in which the eye could be saved.

The doctor put the patient in an eye and ear hospital and there, under a local anaesthetic, performed an operation preparatory to the inserting of a glass eye. The operation included a repair to the eye-socket performed by taking skin from the patient's thigh and transplanting it into the eye-socket. The patient remained at the hospital for about three weeks and upon her dicharge her condition was satisfactory. The doctor intended to perform a second operation upon the patient to correct a shrivelled condition of the patient's eye-lids which had resulted from the burns that she had received from falling on the stove. The patient, however, never returned for such second operation.

Suit was instituted against the doctor in which the claim was made that the doctor's operation had failed to properly prepare her eye-socket so that a "revolving" glass eye could be inserted into the socket, and further that he had failed, as it was claimed he had undertaken to correct by skin graft burns on the plaintiff's face, especially in the region of her eye-lid. The complaint also charged that there was an understanding that the operation was to be performed in strict privacy with the attendance of only the necessary doctors and nurses, and that in violation of this understanding a large number of students were present and observed the operation performed upon the plaintiff while she was fully conscious.

After the case had been at issue for over two years and no steps had been taken on the part of the plaintiff to bring the case on for trial, a motion was made to dismiss for lack of prosecution. The motion was granted, thereby terminating the matter in the doctor's favor,

NEWS NOTES

LETTER TO THE GOVERNOR OF THE STATE OF NEW YORK

The following official letter, to the Governor of the State of New York, is published by direction of the Executive Committee of the Council of the Medical Society of the State of New York:

MEDICAL SOCIETY OF THE STATE OF NEW YORK Fifth Avenue and 103rd Street New York City

December 29, 1932.

His Excellency the Governor of the State of New York, Albany, New York.

Honorable Sir:

The New York Times of Friday, December 23, 1932, carried the following:

Alhany, New York, December 22, 1932.

"Governor Roosevelt announced today that he had turned over to the Aeadeny of Medicine for recommendations and suggestions from a professional standpoint a Special Report on Medical Abuses in Compensation Cases submitted to him by the Committee to Review Medical and Hospital Problems in connection with Workmen's Compensation Insurance submitted by him early last year."

We desire to commend the Sub-committee on Medical Problems under the Chairmanship of Dr. Adrian V. S. Lambert for its very informative report with constructive suggestions made to you on the medical aspects of the Workmen's Compensation Act. We wish, however, to submit our impression that a perusal of the report night lead the reader to believe that all compensation work is done either in "commercial" clinics, or by unprincipled physicians. We are convinced that existing conditions are in fact very bad, the evils involved pertain in a large measure to the Metropolitan area only, and scrutiny of that area does not afford a fair estimate of the application of the Act throughout the remainder of the State.

We respectfully invite your attention moreover to the fact that the Medical Society of the State of New York, with approximately 13,000 physicians as members, is the main official representative body of the medical profession of the State; and we suggest that this Society is therefore the logical body to make "recommendations and suggestions from a professional standpoint" on problems that have to do with the medical aspects and administration of the Workmen's Compensation Act.

The long tradition of the Society, which was incorporated under Legislative Act of April 4, 1806 "for the purpose of regulating the practice of physic and surgery in this State," lends, in our opinion, weight to the views just stated.

our opinion, weight to the views just stated.

Under the sponsorship of the Medical Society of the State of New York, one of its component County Societies, that of New York County, has already established and successfully maintained for eighteen months a Bureau of Compensation Arbitration. This was a practical step forward by organized medicine to correct abuses that had developed in the field of compensation work. The Special Report does not appear to have given consideration to this effort on the part of organized medicine. We feel strongly that the taking of this actual step is an additional reason for consulting the Medical Society of the State of New York in the whole matter.

May we assure you that the Medical Society of the State of New York is willing and indeed eager at all times to place its services at your disposal for the benefit of the State of New York.

Respectfully submitted,

CHAS. GORDON HEYD, M.D., President. Peter Irving, M.D., Assistant Secretary.

REGULATIONS GOVERNING MALPRACTICE DEFENSE AND GROUP INSURANCE

ADOPTED BY THE EXECUTIVE COMMITTEE OF THE COUNCIL OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, JANUARY 12, 1933

Members Not Insured Under the Group Plan:

The Medical Society of the State of New York will furnish to its members the services of the Counsel of the Society in actions brought for al-

leged malpractice, error, or mistake done or claimed to have been done in the legitimate performance of the duties of their profesion as physiciaus under the following regulations: The Counsel of the Society will serve as attorney in all actions for alleged malpractice, brought against members in good standing, who must be so certified by its Sccretary, excepting as follows:

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to membership in the State Society.

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed during a period when they were not in good standing, according to Chapter XIV, Section 4, of the By-Laws.

Members shall not be entitled to malpractice defense while residing and or practicing medicine or surgery outside of the territorial limits of the State of New York.

The Society will not undertake the defense of any member who, after consideration by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide, or any criminal act or who has not complied with the recognized ethical laws in regard to these cases.

Members shall agree not to compromise any claim against them, nor to make settlement in any manner without the advice or consent of the Society given through its attorney.

In the event that a member sued or threatened with suit shall, without the advice or consent of the attorney of the Society, determine to settle or compromise any claim against him, he shall reimburse the Society for the expense incurred in undertaking his defense, and in default thereof, he shall be deprived of further privileges of malpractice defense.

The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims, or awarded by court verdicts, or for making payments for any purpose whatsoever.

Members of the Society desiring to avail themselves of the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing. They shall also furnish the Legal Counsel a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based, giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question, and shall furnish such other relevant information and execute such papers as may be required of them by the attorney of the State Society.

In the event of any difference of opinion between a member of the Society and the Counsel

concerning the eligibility of a claim for defense, or any other matter having to do with malpractice defense or indemnity, all details shall be presented to the Insurance Committee to be referred with recommendations to the Executive Committee of the Council for its decision.

The foregoing regulations are subject to such a change as may from time to time be authorized by the Executive Committee of the Council or the House of Delegates.

Members Insured Under the Group Plan:

All members in good standing shall be entitled to malpractice defense and indemnity in the Group Plan of Insurance on payment of the premium due on the policy selected but the amount of insurance protection granted to any member may be limited at the discretion of the Executive Committee of the Council, subject to petition for reconsideration.

If an assured shall fail to maintain in good standing his membership in the State Society, according to Chapter XIV, Section 4, of the By-Laws, the policy, so far as it applies to such assured, shall be cancelled as of the date upon which he ceased to be a member in good standing. A notice to this effect shall be mailed to the member's last address, and the Company will return upon demand and surrender of his certificate, the unearned premium due him on account of such cancellation. If the member is reinstated by payment of dues, the former policy cannot again be put in force but the member can secure a new policy under the same conditions as if he were a new member of the Society. This rule shall become operative if and when it is written into the policy of the Group Plan.

The Group Plan of Insurance shall insure a member within the limits of his policy against loss growing out of suits or claims for malpractice, error or mistake, committed or alleged to have been committed by an insured member in the legal practice of his profession or by any assistant of such a member, in the treatment or care of a patient previously seen and diagnosed by such a member and for whom the member has directed a

course of treatment or care.

The Group Plan of Insurance shall not cover the liability of an insured member on account of the use of x-ray for therapeutic treatment, the employment of partners, associates, assistants, technicians or nurses to practice medicine in his name independently of his personal diagnosis and specific instructions as to the treatment or care to be given, nor shall it cover the liability which such a member may have by reason of his participation in or ownership in whole or in part of any association, partnership, clinic, hospital, sanitarium, dispensary or any enterprise other than his private practice of medicine. The liability for such participation or ownership constitutes addi-

tional hazards not contemplated under the Group policy or rates, and losses on account thereof shall not be charged against the experiences of the Group Plan. Protection against these bazards shall, upon request and the payment of an additional premium, be furnished by the carrier by endorsement upon member's Group Plan Certificate or under an additional policy of insurance when necessary.

The Group Plan policy shall not cover the liability which an insured member may have an account of injury to patients from causes other than medical treatment, care or advice, nor for injury to persons other than patients from any cause whatsoever. Protection on account of such losses can only be had under general liability or work-

men's compensation insurance.

When in the course of duties imposed upon him as a medical officer of the State, or any political sub-division thereof, an insured member shall be required to render medical opinion, he shall be fully protected under his Group Insurance against the consequences of such an opinion provided it shall have been given to competent authority and not made public by him.

All members in the Counties in Greater New York and Rockland, Westchester, Nassau and Suffolk, desiring insurance protection in the Group Plan of the State Society, shall secure that protection through the Authorized Indemnity Representative of the Society, Mr. Harry F.

Wanvig.

Members Insured by Companies Other Than the Carrier of the Group Plan:

A member who elects to secure malpractice insurance protection from a company other than the Carrier of the Group Plan shall have the same right of defense by the Counsel of the Medical Society of the State of New York as those members not insured provided said carrier is authorized to do business in the State of New York. If

the member desires this service under the circumstances, all the regulations as detailed above applying to members not insured under the Group Plan must be observed. At the time the action is begun and not later the Secretary of the Society shall be furnished with the name of the Insurance Company, policy number, date of policy and amount of insurance carried. There shall also be presented at the same time a letter from an authorized officer of the Insurance Company certifying that the Company will assume the full cost of the defense including the fees of the Counsel of the Medical Society of the State of New York similar to those paid by the Carrier of the Group Plan in like instance. Also that he shall not be required to consult with or receive instructions from the Company as to the manner of defeuse and that the Company will accept his opinion on the final disposition of the action.

As Companies other than the Carrier of the Group Plan usually compel the holders of their policies to accept defense by the Legal Counsel of the Company concerned, the above would not apply. It is essential, however, that members so insured shall also enjoy the benefits of the services of the Counsel of the Medical Society of the State of New York if desired; but it is obvious that such service will be restricted by the rule of the Insurance Company cited above. Thus while the Legal Counsel of the Medical Society of the State of New York cannot be required under these circumstances to assume control of the defense or to appear as associate counsel, he shall be ready to render to the Counsel of the Insurance Company, if requested, a consultant's opinion and advice provided the Company concerned will compensate him for this service in the same manner as the Group Plan Carrier would do if the member was thus insured.

All previous resolutions heretofore adopted, pertinent to malpractice claims and defense, are hereby rescinded.

COMMITTEE ON LEGISLATION, BULLETIN NUMBER 1, JANUARY 13, 1933

This is probably the earliest we have ever issued a bulletin and it forecasts a long and difficult session. We beg of each chairman to make the most of his opportunities immediately to establish a workable contact with his legislators. The following is a list of the members of four important committees with which we can expect to do a good deal of work this winter (page 173).

We shall keep you advised right up to the minute with what is transpiring in Albany and will take the liberty of asking you, individually, when we feel that is the wise thing to do, to make special contacts. There will be great need for lay support this year, and may we, therefore, urge that you immediately enlist the interest of lay individuals in the general cause of medical legislation. If you start now, when a particular occasion arises where the legislators need knowledge of the attitude at home, you will be in a position to bring it out promptly. Remember, the Senate will be under democratic rule and the Assembly republican.

There follows a list of the hills that have been introduced:

Assembly Int. No. 63 - Vaughan, to amend the Penal Law by prohibiting experiments on living dogs. Referred to the Codes Committee. This is the identical antivivisection bill that Mr. Vaughan has introduced for a number of years.

Assembly Int. No. 72—Cooney, to amend the Workmen's Compensation law by providing compensation shall be payable for disabilities or death of an employee resulting from any occupational disease. Referred to the Labor Committee. Note that this amendment extends the law to cover all disabilities that may arise out of industry.

Assembly Int. No. 75—Kantowski, to amend the Workmen's Compensation Law relative to physical examination of employees by striking out provision that physician, as employee or carrier may select and pay for, may participate in examination if employee or carrier so requests. Referred to the Labor Committee.

Assembly Int. No. 102—Breen, amends Conservation Law relative to field meets or trials for dogs. Referred to the Conservation Commission. This bill was carried last year by Mr. Wallace and refers to the mistreatment of animals used in

sports and must not be confused with the antivivisection bill.

Assembly Int. No. 130—Breitenbach, to amen the Workmen's Compensation Law identically a Mr. Cooney offers to do in Assembly Int. No. 72 Referred to the Labor Committee.

Assembly Int. No. 131—Mr. Close reintroduce the lien law bill giving hospitals a lien on an rights of action, suits, claims, etc.. of any perso admitted to hospital on account of personal ir juries resulting from negligence of any person corporation. Referred to the Judiciary Committee. This bill is identical with Assembly In No. 1546, Print No. 1705 of 1932.

Assembly Int. No. 145—Theodore, amends the Workmen's Compensation Law by permitting in jured employee to request employer to furnish medical attendance or to furnish attendance him sent at expense of employer. Referred to the Labor Committee.

HARRY ARANOW,
JOHN J. BUETTNER,
B. WALLACE HAMILTON
B. B. BERKOWITZ,
EDWARD E. HALEY.
Committee on Legislation.

LEGISLATIVE BULLETIN NUMBER 2

January 20, 1933.

Since our last bulletin the following bills have been introduced:

Senate Int. No. 143—Berg (Assembly Int. No. 354—Rice). Senator Berg offers to amend the Education Law so as to permit restoration by the Regents of a license to practice medicine, to a person pardoned after conviction of felony. At present the law prevents the restoration of the license if conviction has been for misconduct in his professional capacity. Mr. Berg's amendment would delete this exception. You will recall he had this bill before us last year and we opposed it then. Give us your reaction this year. Referred to the Education Committee.

Senate Int. No. 184—Mr. Berg again asks that the Education Law be amended by extending for six months after May 17, 1933, time for applying for license to practice physiotherapy by those who have not taken the four-year course of instruction now required by law. Referred to the Education Committee. We see no reason why this amendment should be made. If there are persons who wish to practice physiotherapy, they should qualify for licensure in the regular way. Do you agree with us?

Assembly Int. No. 181—Bernhardt's antivivisection bill. He would amend the Penal Law by making it a misdemeanor to experiment or operate on a living dog for any purpose other than healing or curing the dog without the owner's permision in writing. Referred to the Codes Commitee. You will note that this would make it illeg for even a veterinarian to do anything with a dt without having a written permit from the owne Mr. Bernhardt has also introduced a resolutic calling for an investigation of the laboratories the state and appropriating \$25,000 for the expenses thereof. This resolution was referred the Committee on Ways and Means.

Assembly Int. No. 246—Mr. Lewis offers amend the Public Health Law by reducing the compensation of a health officer of a city, town village or district with population of 8,000 cless. At present the law specifies that such healt officer shall be paid not less than 15c per capit per inhabitant per annum. Mr. Lewis suggesthat the minimum shall be 10c. Referred to the Health Committee.

Assembly Int. No. 328—Mr. Close woul amend the Criminal Code, providing rule as a compensating witnesses attending before corone or medical examiners shall be same as prescribe by law for attendance of witnesses before a cour or judge. Referred to the Codes Committee.

Assembly Int. No. 329—Mr. Cohen would create a temporary commission to study the administration of the Workmen's Compensation Law and appropriates \$15,000. Referred to Way and Means Committee.

Assembly Int. No. 331—Mr. Hayes offers to amend the Civil Service Law by giving war nurses same protection against removal now given veterans and volunteer firemen and providing no position held by any of them shall be abolished while its duties continue to exist in that branch of public service. Referred to the Judiciary Committee.

Assembly Int. No. 342—Messer, to amend the Public Welfare Law by requiring public welfare district to provide necessary medical care for all persons unable to maintain themselves. Referred to the Judiciary Committee. Mr. Messer changes the definition of persons eligible for relief as follows: "The public welfare district shall be responsible for providing necessary medical care for all persons under its care and for such persons otherwise able to maintain themselves who are unable to secure necessary medical care" to read: "*** for all persons who are unable to maintain themselves."

Assembly Int. No. 345—Mr. Neustein would amend the Education Law by providing in New York City every place in which drugs, chemicals, medicines, prescriptions or poisons are retailed or compounded, shall be a pharmacy and under personal supervision of a pharmacist. Referred to the Education Committee.

Assembly Int. No. 346—Mr. Neustein would amend the New York City Inferior Criminal

Public Health

Courts Act, by enlarging jurisdiction of courts of special sessions held by City magistrates to include violation of Art. 22, Public Health Law, where defendant is charged with possessing narcotics and pleads guilty. Referred to the Codes Committee.

Assembly Int. No. 362—Bartholomew, adds a new section to the General Municipal Law, permitting supervisors of county not wholly in a city to terminate by two-thirds vote all child welfare allowances in which case the child welfare board shall be deemed abolished. Referred to the Indiciary Committee.

In response to our request, we have had information correcting our mailing list of county chairmen in two instances. Are there any others?

At a meeting of your Committee yesterday, a program was outlined calling for more intensive work from every county chairman this year than in previous years. The type of legislation which we anticipate will give us the greatest concern will relate to modifications of the Compensation Law. We especially urge, therefore, that every chairman read carefully the bills that relate to compensation, so that we may have most effective support when the time comes to take action.

Labor and Industry

GREENE COUNTY

The regular meeting of the Greene County Medical Society was held at the Saulpaugh Hotel, Catskill, at 8 P. M. on January 21, 1933.

A dinner preceded the meeting, with about forty per cent of the membership present.

Dr. Elisha B. Van Deusen of Catskill was elected to membership, and the application of Dr. William V. Wax of Catskill was referred to the Comitia Minora.

Drs. Edgar Vander Veer, James Vander Veer, Joseph Cox and Mr. Thomas Murray, Superintendent of the Memorial Hospital of Albany, were guests of the Society and presented a symposium on Hospital Staff organization, manage-

ment and equipment. This symposium was at the request of the Society in preparation for the opening of the new Greene County Memorial Hospital which is now nearing completion, and in which the organized profession proposes to take an active part.

It was decided to erect a memorial bronze tablet in the lobby of the hospital if a suitable plan and prices could be secured. To effect this the President appointed Drs. Atkinson, Daley and R. E. Persons a committee to draft the plan and to secure prices.

WILLIAM M. RAPP, Secretary.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall on December 21, 1932, was called to order at 8:50 P.M., the President, Dr. Klein, in the Chair.

Drs. Emanuel Feit, Joseph H. Hillman, Nathaniel T. Kwit, Emanuel J. Richter, Lionel C. Rubin and Abraham Werner were elected members.

In accordance with the recommendation of the Comitia Minora, Dr. Gustav H. E. Starke was elected Honorary Member of the Bronx County Medical Society.

Dr. Lefcourt presented the Report of the Social Committee. He appealed for the cooperation of the members in making the Beefsteak and Show, to be held on January 25th, a great financial, as well as social, success. The proceeds will be devoted to our relief fund.

Dr. Podvin, Chairman of the Special Committee on Baby Welfare, described in detail the work being done by the Committee. He asked the members for their cooperation and for any criticism they may desire to make. He emphasized that the work now being done by the Committee on Public Health, in connection with the Examination of High School students, as well as the work of his Committee. demonstrates how social welfare work can be done under the auspices of the County Society. These projects are now being carried out very successfully under our supervision, and it is felt that as a result other benefits will accrue to the profession and to our Society far greater than we imagined in the beginning. The Scientific Program then proceeded as follows:

"Interpretation of Abdominal Pain," by Dr

Edward M. Livingston.

The Paper was discussed by Drs. S. Philip Goodhart, Alexander Goldman, William Weinberger and Henry Roth. Dr. Livingston closed the discussion.

> I. J. LANDSMAN, M.D., Secretary.

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall on January 18, 1933, was called to order at 8:45 P.M., the President, Dr. Klein, in the Chair.

Drs. A. Edward Balboni, Bernard Isaacson, Peter Kleinkopf, Joseph Lozner and Louis Rosenberg were elected members.

Reports of committees being in order, Dr. Frank, for the Social Committee, reminded the members of the Beefsteak Dinner and Show, to be held on Wednesday evening, January 25th, the proceeds of which will be devoted to our

Relief Fund. He appealed for the cooperation of all the members.

Memorial resolutions in honor of Dr. Sydney Steiner were adopted.

An address on "Group Practice in the United States: Retrospect and Prospect," was given by Dr. Morris Fishbein, Editor, Journal American Medical Association.

This address and our own plan to establish private group clinics in the County of The Bronx were then discussed by Drs. Nathan B. Van Etten and Benjamin H. Archer.

I. J. LANDSMAN, M.D., Secretary,

ROCKLAND COUNTY

Forty-one members of the Medical Society of the County of Rockland turned from scientific subjects to their Annual Banquet, which was held on Wednesday afternoon, December 7, at the Hotel St. George, Nyack.

Good music and splendid entertainment helped to make the afternoon a pleasant occasion.

Guests present from the Westchester County Department of Health were Doctors Matthias Nicoll, Jr., Commissioner of Health: Edward H. Marsh, Deputy Commissioner; and Eugene W. Bogardus, Director, Division of Tuberculosis.

All officers of the County Society for the previous year were re-elected:

President, Dr. S. R. Monteith. Vice-President, Dr. George M. Richards. Treasurer, Dr. Dean Millimore. Secretary, Dr. William J. Ryan. Chairmen of Standing Committees: Membership, Dr. G. F. Blauvelt.

Legislative, Dr. C. D. Kline. Public Health and Public Relations, Dr.

Royal F. Sengstacken.

Physical Therapy, Dr. Leo G. Weishaar. Medical Economics, Dr. Julius Pomerantz.

Dr. Russell E. Blaisdell of Orangeburg, was appointed a member of the Board of Censors-to fill the unexpired term of Dr. R. R. Felter, terminating in December, 1933.

Dr. Alfred M. Stanley, Dr. Harold H. Dodds. and Dr. Leo P. O'Donnel, all of the Rockland State Hospital, Orangeburg, were admitted to membership on this date.

The Treasurer reported that there was \$919.12 in the treasury and that the Society's membership was fifty-nine.

It is interesting to note that there is but one practicing physician in Rockland County who is not a member of the County Medical Society.

WILLIAM J. RYAN, Secretary.

THE DAILY PRESS

DR. WILLIAM H. PARK

Family physicians will approve the following editorial which appeared in the New York *Times* of January 20th:

"For more than a generation Dr. William H. Park has been head of the Health Department's laboratories and Professor of Bacteriology and Hygiene at New York University and Bellevue Medical College. Obviously, it marks no turningpoint in his career when he transfers to the new Hermann M. Biggs Chair of Preventive Medicine without making any change in his Health Department activities. The late Dr. Biggs was his predecessor, his chief and his collaborator in what was probably the most useful single case of gainful occupation in our times in New York.

"We speak of the world being transformed

beyond recognition by automobiles, wireless and airplane. But what a different world it is today, when diphtheria takes one child for every 100,000 people, from what it was in 1895, when diphtheria killed 150 times as many children! To have gone through forty years of campaigning against tuberculosis with impressive victories; to have seen the death rate for the general population cut in two; to be living in a world where infant mortality is one-sixth of what it was a generation ago, is to witness changes indeed. To have had an active hand in the furtherance of these changes is to have made history in a very real sense.

"The career of a public servant like Dr. Park helps to explain why people put up with political organizations."

POPULAR FALLACIES

The New York Sun of December 29 discusses popular fallacies in the following editorial:

"Two of the eminent scientists at Atlantic City, taking stock of the state of knowledge, have catalogued 'eight popular beliefs that are not true' thus:

"'A child is influenced by what its mother sees or thinks before the child is born;

"Birth marks are caused by what a mother sees or touches before her child is born;

"'In former times the average length of human life was much longer than now;

"'Fat people always are good natured;

"'Mental disorders are caused by over-study;
"'Children of first cousins, though of good parentage, are likely to be feeble minded;

"'Heavy growth of hair on a person's limbs and chest indicates great physical strength;

"'The theory of evolution implies that men are

descended from apes.'

"This list of beliefs unbased in fact is particularly interesting because each of its items is a

venerable cumberer of the human mind.

"A belief once accepted by the population at large has more lives than a litter of kittens. The earnest inculcator of sound doctrine who attempts to dislodge it undertakes an almost hopeless task. Nor does this mean that truth is mocked. The intruth is simply, often picturesquely, dressed; the exceptional circumstances that seem to support it are vividly related and remain in the memory, while the gown of truth is likely to be a drah garment stitched with ifs and buts."

A PROMINENT ANTI-VIVISECTIONIST

The New York *Herald Tribune* of December 29, carried an obituary of Dr. W. R. Hadwen, an anti-vivisection leader, of Gloucester, England, who died on December 28, aged 78 years.

The article says:

"Dr. Hadwen devoted his career to the vigorous opposition of two medical practices—the dissection of living animals and vaccination—and the enthusiasm with which he waged his campaigns drew wide attention on both sides of the Atlantic. The force of his utterances was strengthened by the fact that he held the degree of doctor of medi-

cine from the University of St. Andrews, Scotland, was a member of the Royal College of Surgeons, a licentiate of the Royal College of Physicians and of the Society of Apothecaries.

"Behind Dr. Hadwen's animosity toward vivisection and vaccination was a profound belief that the whole theory of medicine was built upon false premises. Among their beliefs he held that germs had no causal relation to disease, a theory that he fully explained in 1924 in an article en titled 'The Doctor and His Conscience.'

"Comparing himself to Harvey and Semmel-

weis, heroes of medical history who were indicated in their day. Dr. Hadwen wrote

"The germ theory of disease declares that a specific germ is the origin of every specific disease. I his, in other words, means that, when man was created, microscopic beings were created at the sime time to prey on and destroy the highest form of created life. This gives the impression that not only are higher eretures placed in the world for a useful purpose, but that other creatures are

placed there for the purposes of terrible evil Now this, in my opinion, is completely contrary to the whole design of a good and all wise Creator

"Members of the New York Anti Vivisection Society expressed regret yesterday at his death Mrs Diana Belais, founder and president of the local organization, characterized him as 'a great and powerful factor in the movement,' saying that his support 'was vital to a cause so frequently condemined by the majority of MD's'."

HEALTH ZONING

A new form of health zoning for New York State is outlined in the New York Herald Tribunc of December 20, as follows

"The creation of a new health zoning system throughout the state and the possibility of greater centralized control of highway construction and maintenance as stibstantial economy measures were considered yesterday at an executive session of the Legislative Tax Revision Commission, headed by Senttor Seabury C Mastick, at the Bar Association Building, at 42 West Forty-Fourth Street

"It was proposed, said Senator Mastick, that the state be divided into five health zones embracing all the various welfare agencies now existing in these suggested divisions, and that the entire system be placed under one head. The proposal, the charman explained, would climinate much current displacation and substantially reduce present

health costs

"It is proposed, therefore, to divide the state up as follows

"1 A state district under state administration comprising either parts or the whole of the ten counties in the Adirondack Mountinus section

"2 A city district for Buffalo

"3 City-county districts in which the city and county health departments are unified for the large eities and their counties, with New York City excepted

'4 County districts where the population is

sufficient to minintain a health district

"5 County consolidated districts wherein certum adjacent counties would consolidate to provide the requisite population

"Such a plan, Mr Mastick added, would give the state forty eight health districts outside of

New York, under central supervision

"New York City is not considered in the plan, because it is capable of sustaining itself."

SOCIALIZED DENTISTRY

The attitude of dentists towards the report of the Committee on the Costs of Medical Care is shown by the following news item from the New York Herald Tribune of December 8, 1932:

'Socialized dentistry was discussed by several speakers at yesterday's sessions of the Greater New York December Meeting for Better Dentistry at the Hotel Pennsylvania Dr John T Hanks, of New York City, said

"The dental profession is about to be faced with a proposition politically sponsored to set in socialized dentistry, and in order to anticipate such a move the profession should get up its own plan, so that if it is put into operation only the highest ethical standards would govern it, under the control of the dental profession and not by politicians."

"He pointed out that if such a plan were worked out and if i compulsory health insurance law were enacted, the profession could demonstrate that it already had its own plan working and that such a law should be fitted to it.

"The dental profession could organize a service that would make compulsory health in shrance unnecessary, he argued, and he emphasized that such plans would refer only to the care of low income groups and would not affect patients with financial ability to care for themselves

"He warned that a policy of complete opposition to insurance dentistry might put the medical and dental professions, if and when laws were formulated, in the same position as the professions in European countries, where, he said, they were ignored in the framing of the legislation which was dictated by the insurance carriers

"Dr Matin Dewey, past president of the American Dental Association criticized the report of the Committee on Cost of Medical Care contending that 40 per cent of the amount paid by the public would be used in administrative expense and only 60 per cent for actual medical service that is delivered to the people."

BOOK REVIEWS

A CORRECTION

The department of Book Reviews in the JOURNAL of January 15, 1933, page 119, carried a review of a book on "The Gastrointestinal Tract" by William Gerry Morgan, M.D., Philadelphia, but the heading was that of another book entitled "Functional Disorders of the Large Intestine and Their Treatment" by Jacob Buckstein, M.D., New York. These two reviews are printed below under their proper titles. Editor's Note.

Gastrointestinal Tract. By William Gerry Morgan, M.D. 12mo of 259 pages, illustrated. Philadelphia, J. B. Lippincott Company, [1931]. Fabrikoid, \$5.00. (Everyday Practice Series.)

This work, one of a series of books edited by Doctor Harlow Brooks, has been written for the general practitioner. The author, who realizes that a dissertation on functional gastrointestinal disorders would hardly fill even a small volume, has taken the opportunity to present much of value in other directions. In Part One he gives a brief. yet comprehensive survey of gastrointestinal physiology and goes at length into the important question of history taking and physical examination. In all the discussions of the so-called gastrointestinal neuroses, the author is very careful to emphasize that a diagnosis of a functional disorder must be made only after the most complete study of the patient has disclosed no lesion accounting for the symptoms. The book is replete with reports of cases treated by the author in accordance with his recom-mendations, and a careful study of his findings often reveals that an organic condition was the cause of trouble. Part Three, on "Motor-Sensory Neuroses of the Intestine" consists largely of a discussion of organic lesions such as duodenitis, colitis and proctitis with some men-tion of vagotonia as a cause of colonic disorders. The chapter on constipation is excellent, that on visceroptosis rather poor. As a whole, the book is apt to be misleading to a general practitioner, even though the case histories are illuminating.

Functional Disorders of the Large Intestine and Their Treatment. By Jacob Buckstein, M.D. 16mo of 265 pages, illustrated. New York, Harper & Brothers, 1932. Fabrikoid, \$3.00. (Harper's Medical Monographs.)

The term "functional" applied to disorders of the gastro-intestinal tract is usually a cloak for ignorance of the actual nature of the lesions causing symptoms. This very excellent little book has apparently been written for the purpose of dissipating some of this ignorance. The first chapter is one of the best treatises on the embryological development, the anatomy, and the physiology of the large intestine that has yet appeared. Following this, functional disturbances are discussed, not per se, but for the purpose of calling attention to the structural changes causing them. The book is replete with refcrences to the literature, and such subjects as membranes and adhesions, mucous colitis, allergy and the effect of extraneous diseases upon colonic function are adequately The recommendations regarding treatment show considerable clinical acumen, although at times they are somewhat empirical. On the whole the book can be recommended as one taking a very conservative view of the subject it treats.

Intracranial Tumours. Notes Upon a Series of Two Thousand Verified Cases with Surgical-Mortality Percentages Pertaining Thereto. By Harvey CushING. Quarto of 150 pages, illustrated. Springfield, Charles C. Thomas, 1932. Cloth, \$5.00.

This book represents another masterpiece by the outstanding neuro surgeon and teacher of this subject. This monograph is the result of a study of over 2,000 cases of brain tumors, a report of which was presented before the International Neurological Congress in Berne, Switzerland, in September, 1931. It represents a time consuming task which only the author can really appreciate. The classification, description, notes of interest and cases illustrating valuable points of information, have been so clearly and carefully worked out that we can state without hesitation, that this book is the only one of its kind. It is so valuable that every neurologist and surgeon interested in brain surgery should add it to his collection and consult it freely.

O. C. Perkins.

Mental Deficiency Due to Birth Injuries. By Edgar A. Doll, Ph.D., Winthrop M. Phelps, M.D. and Ruth Taylor Melcher, M.A. Octavo of 289 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$4.50.

The authors present case material exhibiting mental deficiency, more or less directly traceable to cerebral injuries apparently sustained at birth. In every instance in this series, mental deficiency has been associated with motor paralysis.

The essential points studied were, the consequences of birth injury relative to mental deficiency and motor handicap; development of a reliable method of testing such children mentally. In the latter field, the Binet-Simon and Myers Mental Measure were found to offer the best technique for mental study of these children. Other points studied were the value, mentally and physically, of physical therapy, especially motor re-education. Lastly, the authors present for consideration, the question of whether or not, the limitation of movement and speech inhibit the intellectual development; if so, removal of these motor handicaps by physical therapy, may be followed by an increase in expressive intelligence.

The book is well organized. There is a detailed presentation of the etiology and symptoms of birth injury; also excellent chapters on the mental testing of such cases and finally physical therapy. Case histories are appended. Very important also, for those who may be students of the subject, is an extensive bibliography.

This book is recommended highly for perusal by all physicians.

STANLEY S. LAMM.

Your Teeth and Their Care. By Carl W. Adams. D.D.S. 12mo of 141 pages, illustrated. St. Louis, Mo., C. V. Mosby Company, 1932. Cloth, \$1.25.

This small but concise book is a very well written treatisc on an important subject that should interest every lay person as well as the profession. It has a good deal of interesting and excellent material in regard to the teeth.

The first half of the book, which contains four chapters, is devoted to a description of the anatomy and physiology of the teeth and oral tissues. This part of the book will not be very clear to the lay public because of the technical discussion of the histology and etiology of tooth disease.

The second part of the book, which is about oral prophylaxis, relation of diet to the teeth, and explanation of dental procedures, is much more readable and understandable by the average person. The chapter on oral

prophylaxis contains a good deal of sound advice on the use of tooth brushes, month wash, dental floss and tooth

It is about time that dental authorities inform the gullible public of the scientific truth in regard to teeth, month washes, and dentifrices, to counteract the many immerited and exaggerated claims made through the commercial media of newspapers, magazines and radio. This book ought to find a good deal of favor by the in-telligent public and is of especial interest to the dental OSCAR RODIN. hygienist.

THE AMERICAN LILUSTRATED MEDICAL DICTIONARY. BY W. A. Newman Dornann, M.D. Sixteeuth edition. Octavo of 1493 pages, illustrated. Philadelphia, W. Octavo of 1493 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Flexible and stiff binding, plain, \$7.00. Thumb index, \$7.50.

This dictionary has been before the medical profession for thirty-two years. During this time it has been kept up-to-date by constant revision—sixteen editions having appeared.

It needs no introduction to workers in the field of medicine. It has established itself as a standard working tool in the equipment of the physician.

This latest edition has been prepared under the editorial supervision of the staff of the American Medical Association, with the collaboration of Doctor E. C. L. Miller. It is stated that more than three thousand new words have been included in this revision, hundreds of which have not been defined in any other medical dietionary. All the essential fundamental factors that go to make up a standard dictionary are incorporated in this work. To its many excellent features, there have been included in this edition, for the first tine, the portraits of two hundred and seventy-nine outstanding physicians of the past. This adds to the attractiveness and historical value of the work,

One of the commendatory features is that, in spite of its nearly fifteen hundred pages, it has been kept within a compact, easily handled volume.

For a complete, well arranged, well balanced, up-todate medical dictionary, we heartily recommend

TREATMENT OF SYPHILIS. By JAY F. SCHAMBERG, M.D. and CARROLL S. WRIGHT, M.D. Octavo of 658 pages, illustrated. New York, D. Appleton and Company, [c1932]. Cloth, 88.00.

This should be a widely consulted book as it is the first book in American medical literature to deal alone with the treatment of syphilis. Needless to say, the authors have presented the subject matter in a highly practical manner. A history of the use of each drug is interesting. Opinions of the results of treatments with various combinations by many authorities are pre-sented and finally the authors' methods,

The chapter on the treatment of syphilis in pregnancy should be of especial interest to the obstetrician. Chapters on syphilis and marriage, and other social aspects of the disease supplements the 600 page volume.

Thurshan B. Givan.

PULMONARY TUBERCULOSIS. By MAURICE FISHBERG, M.D. Fourth edition, thoroughly revised. Octavo, two volumes, totalling 1191 pages, illustrated. Philadelphia, Lea & Febiger, 1932. Cloth, \$15.00.

Dr. Fishberg's Fourth Edition of "Pulmonary Tuberculosis" more than fulfills all the high values we have come to associate with his writings. Again, the book has been most thoroughly overhauled and in a very large part truly rewritten. Barring a few exceptions which we will mention later, this work is to our mind incomparably the best on pulmonary tuberculosis written in the English language.

Without question, Dr. Fishberg is a profound student of his subject, and from his vast store of accumulative knowledge, he presents every possible known viewpoint on each of the several subjects he discusses. This Fourth Edition is even better than the Third. We note that he has dropped his previous classification of "Abor-tive Tuberculosis," the term that always struck us as being a bit gratuitous. In his chapter on the "Tubercle Bacilli," we are surprised that he makes no mention of the important work at present being conducted on the dissociation of types. The chapters devoted to "Tuber-culous Infection," "Predisposition," "The Phenomena of Immunity," and "Pathology and Morhid Anatomy" are admirable.

Only in the later chapters devoted to treatment do we find ourselves unable to subscribe io whole to the opinions of the author. Some of the statements he makes are so at variance with those of the vast majority of well-recognized workers in the field, that one is forced to assume that the burden of the proof of many of the author's statements must be placed squarely upon him. Particularly do we dissent from the view that less than five per cent of all cases of clinical pulmonary tuberculosis are suitable for collapse therapy. We realize that in certain portions of the country the advocates of collapse therapy are running a bit wild, and possibly some such stand as that taken by Dr. Fishberg is a wholesome one in holding our more radical friends in cheek. The successful application of collapse therapy lies somewhere in the mean between these two extreme schools. FOSTER MURRAY.

POSTURE, ITS RELATION TO HEALTH. By FRANK D. Dickson, M.D. 12mo of 213 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1931. Fabri-koid, \$5.00. (Everyday Practice Series.)

If the average physician were to record his knowledge of posture one could be fairly certain that it would not require a 207-page volume. This is no reflection on the desire for the possession of such information, but is a reflection on the dearth of concentrated information on the subject in our medical literature. Books on massage and gymnastics are too technical, and of particular interest to those in semi-professional callings, whereas, medical literature in general often dismisses the correction of posture with a perfunctory phrase or too-rarely insufficient detail to provoke enthusiasm for its possibilities.

We are all aware of the deleterious effect of poor posture in a great number of subacute or chronic ailments, such as arthritis and tuberculosis. What we are not so well informed about is the markedly beneficial effect of the correction of such defects in the management of disease. Our notions regarding proper body balance, good body mechanics, and corrective exercises, are vague. An office formula to an inquiring parent regarding what should be done about the child's posture is very likely to be the terse expression, "have him stand up straight." There is, however, more to the ham stand up straight. I free is, however, more to the story than that, and this volume is the only one we have read which gives a concise, practical, and interesting exposition of the proper answer.

The author does not make extravagant claims for the effect of this element on the cure of disease, but he rightly iosists that the profession has been very neglectful of its importance. In a convincing, easy style he explains the relationship of posture to visceroptosis, with its resultant gastric disorders and constitution; to arthritis, especially the hypertrophic type; to backache, neurasthenia, and malnutrition. Read it-you will have occasion to use the information gained many times a D. E. McKenna.

OUR NEIGHBORS

THE COMMONWEALTH FUND AND THE FAMILY DOCTOR

The Journal of the American Medical Association of December 31, 1932, prints the following letter from Mr. Barry C. Smith, General Director, The Commonwealth Fund, whose headquarters are at 41 East 57th Street, New York City:

"In the issue of The Journal for December 3 appears an able editorial on the Committee on the Costs of Medical Care. In this editorial are references to 'the eight foundations that contributed financial support' and also, later in the editorial, on page 1952, a further reference to 'the great foundations' as supporting the principle of socialized medicine.

"In order that members of the medical profession may clearly understand that the Commonwealth Fund is not included among the foundations mentioned, I should like to make the following statement:

- "1. The Commonwealth Fund, although repeatedly requested to do so, has not made any appropriation directly or indirectly to the Committee on the Costs of Medical Care.
- "2. The Commonwealth Fund does not subscribe to or approve of the program of the majority report looking toward the establishment of socialized medicine.
- "3. The Commonwealth Fund agrees fully with the attitude expressed by the minority report on the subject of public health, as stated in the second paragraph on page 152 of the minority report.

"The policies of the Commonwealth Fund in its public health work are given in detail in the book Child Health and the Community, published by the Fund in October, 1931, which received lengthy and favorable comment in The Journal, Jan. 2, 1932.

"I write this letter not for the purpose of criticizing any person or group of persons but solely in order that practicing members of the medical profession may have a clear understanding as to the attitude and policy of the Commonwealth Fund toward the profession and its work."

The review of the book "Child Health and the Community," to which reference is made in Mr. Smith's letter, is as follows:

"Of particular interest is the statement by Barry C. Smith, general director of the Commonwealth Fund, referring to the place of the private physician in such a program. Mr. Smith says:

"'In one particular, the Fund considers itself most fortunate. It enjoyed, at all times, a high

degree of cooperation with the practicing medical profession.

"'Upon our medical schools must rest the responsibility—a great one—for training the future physician in the principles and technics of preventive medicine and of public health, and of making clear the indispensable service which the private physician must render to these activities if they are to be fully successful. Upon the public health worker rests the responsibility for showing a patient and cooperative attitude toward those from whom he expects such an attitude.'

"The chapter on physicians reveals still further the way in which this demonstration sought for medical cooperation. The general impression seems to be that medical practice improved, particularly as related to children, following the demonstrations. Indeed, the statement of principles which seem to be fixed premises for any permanently successful community program of preventive medicine and public health merits quotation in full:

"1. The public interest must be paramount. This is a general statement to which almost any one will agree until the ideas of others as to the public interest come into conflict with his own ideas as to his private interests.

"2. The interest of any group that is contributing to the solution of a public problem must to that extent be considered a public interest.

- "3. Physicians constitute a body of citizens whose training has prepared them to render a service to public health for which there is no adequate substitute.
- "4. Physicians in private practice perform a service in the treatment of disease, whether as individuals or in fully organized groups, whether in private offices, clinics, hospitals, or homes, that is the accepted mode of treatment, in this country, for those able to pay for such service.
- "5. Physicians in private practice, because of their training, numbers and relationships to their clientele, constitute the one group which is potentially most capable of applying the lessons of preventive medicine to the habits and circumstances of the individual. They are largely unprepared to render such service because their training and experience have been chiefly therapeutic.
- "6. The public is largely unready to demand or pay for such guidance in the application of the lessons of preventive medicine to personal problems.

 (Continued on page 182—adv. xiv)

-the primary form, carotene, of vegetable origin

CAROTENE PRIMARY VITAMIN A

Carotene (primary vitamin A) is the essential food factor provided by nature to meet certain important bodily requirements and is

necessary for the synthesis of secondary vitamin A by the liver. Carotene is to vitamin A therapy what sunlight is to vitamin D therapy.

.. to make sure your patients get PRIMARY vitamin A, prescribe Smaco Caritol . . (Carotene in vegetable oil) Product No. 505

ALONI: or with any of these products:

- Plain or flavored cod liver off.
- Cad liver all with viceteral 10.D.
- · Viceteral 250 D.
- Halibut liver oil, plain, or with vioaterol.
- Sunshine or ultre-violet light therapy.
- Cod liver oil concen-trates or tablets.
- Smaco Concentrated Vitamin D.

a 0.3% solution of carotene in vegetable oil . . absolutely no fishy taste . . deep red color . . 15 c. c. and 50 c. c. protectively colored bottles . , small five to ten drop dosages . , high potency . . use alone or with other forms of vitamin therapy.

. . . . for the greatest ECONOMY, prescribe Smaco Cod Liver Oil fortified with carotene and natural vitamin D, Product No. 510

High grade cod liver oil fortified with carorene (primary viramin A) . . . therefore contains both primary and secondary viramin A . . . also fortiled with Columbia Zucker natural viramin D. . . three times as potent in both A and D, one teaspoon equivalent to three teaspoons of standard potent cod liver oil . . . improved flavor, more palatable . . . smaller doses . . . minimum cost to the patient.

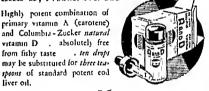

Cod liver oil, halibut liver oil and other fish liver oils do not contain carotene (primary vitamin A) and the secondary form which they do contain, cannot be converted into pri-

mary vitamin A. Carotene should be prescribed either alone or with other vitamin products.

for patients who object to taste or bulk of end liver oil, prescribe Smaco Vitamins A and D. Product No. 325

primary vitamin A (carotene) and Columbia - Zucker natural vitamin D , absolutely free from fishy taste . ten drops may be substituted for three teaspoons of standard potent cod liver oil.

for vitainin D alone (for the prevention or cure of rickets), prescribe Smaco Concentrated Vitamin D. Product No. 515

Highly potent, natural vitamin D prepared by methods (Zucker process) developed at Columbia University... mot a cod liver oil concentrate, not an irradiated product, but rather a highly potent extract of the antirachitic principle of eod liver oil . . . ten drops equivalent in D potency to three teaspoons of standard potent cod liver oil.

"7. An honest, consistent and cooperative effort should be made by the organized medical profession, the health authorities, and private groups interested in public health to develop public demand for preventive services by private physicians whether practicing as individuals or in organized groups.

"8. An inseparable corollary to this effort should be the conscientious preparation of physicians for such services, without which the attempt to build up satisfactory preventive services by private practitioners is doomed to failure.

"9. Health conferences or preventive health center medical services conducted by the health department, especially for babies and younger children, are justified and desirable (a) as a means of creating a demand for such services, (b) as an agency for inaugurating proper standards for such services, (c) as a practice ground for physicians in the art of preventive medicine, and (d) as a supplement to the preventive services of private practitioners, so long as conscientious efforts to make such services adequate to the public needs have not been successful.

"10. The paramount interest of the public must come to the fore especially in any question of the control of communicable disease. Leaving to the private practitioner as much latitude as possible in all discretionary matters of treatment, the health officer should take responsibility for promoting such immunizations as are accepted as part of the necessary protection of the community and must assume final authority for all control measures and for diagnosis in so far as that is necessary to insure prompt and accurate recognition of cases.

"It would be well if the point of view here set forth by the Commonwealth Fund would be used to guide similar groups whose interests affect both the medical profession and the public."

PAY FOR AUTO ACCIDENTS IN MISSOURI

The Journal of the Missouri State Medical Association discusses collections for medical services after automobile accidents in an editorial, as follows:

"The Economic Survey Committee of the St. Louis Medical Society presented an exhaustive report to the Society at the meeting of December 13 on 'Automobile Accidents and Emergency Treatment.' In this report which was adopted by the Society the committee recommended that the Society request the Missouri State Medical Association to draft a bill for introduction in the 1933 session of the legislature with the view of providing a reasonable assurance of the payment of fees of physicians and hospitals for services rendered

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization — with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Fellows' Syrup contains the mineral salts of sodium, caleium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

in emergencies growing out of automobile accidents. The committee proposed that this protection take the form of a lien upon any moneys received by the person responsible for the accident as payment of liability damages.

"The introduction of such a bill in the legislature was one of the major recommendations of Dr. J. F. Harrison, Mexico, in his presidential message to the House of Delegates at the Jefferson City Session of our Association in 1932; and the Committee on Public Policy was instructed to draft such a bill and introduce it in the 1933 session of the legislature. The action of the St. Louis Medical Society will materially strengthen the movement and its cooperation with the State Association committee will be invited.

"Lien laws to protect physicians and hospitals have been adopted in six states, viz., Delaware, Montana, Nebraska, New Jersey, Oregon and Virginia. Montana and Nebraska are the only states in this group that mention physicians, nurses and hospitals as entitled to liens. The other states limit the liens to hospitals, 'supported in whole or in part by private charity' in Delaware; 'supported in whole or part by private charity or maintained by municipal county board' in New Jersey; 'hospitals' in Oregon; and 'in hospitals, public or private,' in Virginia. During 1931 lien laws were introduced in the legislature of ten other states but the bills failed of passage. Nebraska was the first state to adopt the lien law in behalf of physicians and hospitals; this was done in 1927. It was not until 1931 that the attempt to pass lien laws was renewed and in that year Delaware, Montana and Oregon adopted the law, Virginia following with the adoption of the law in 1932. It is quite probable that the effort will be made to pass lien laws in many of the legislatures in 1933 ses-

"Compensation for injuries sustained in motor vehicle accidents has been under consideration by various state legislative bodies in the last few years. A number of states have enacted financial responsibility laws (not lien laws). These laws have been designed in part to increase gradually the number of financially responsible owners and drivers by requiring those who have been responsible for accidents to be insured. Massachusetts has a compulsory liability law requiring all motor vehicle owners to be covered by insurance against liability for personal injuries.

"In compensation for injuries the question of how people meet the expenses caused by motor vehicle accidents looms large and of course depends upon whether the injured per-

(Continued on page 185-adv. xvii)

(Continued from page 184-adv. xvi)

son was struck by an insured motorist or by one who was not insured. The report of a committee to the Columbia University Council for Research, February 1, 1932, says a study of cases not covered by insurance indicates that the injured person has about one chance in four of receiving some payment and that in most cases the payments will not cover the losses sustained. It is very evident therefore that when the person responsible for the accident is not insured the physician or hospital has a very remote chance of collecting ices for services. However, 'if the offending motorist is insured,' says the report just mentioned, 'payment will be received in 85 per cent of the cases.' Again, since only about 331/3 per cent of all motor vehicles are insured it is evident that the chance for collecting the fees in all cases is materially reduced.

"The committee of the St. Lanis Medical Society found no information concerning surveys made by other medical societies relating to this problem, but recently in Philadelphia thirty-five hospitals were surveyed, eighteen reporting data covering 688 cases treated in 1929. Sixty-two per cent of these eases received free treatment. Bills were rendered in 259 of the 688 cases and 50 per cent of these remained unpaid at the end

of one year.

"In 1930 the Ohio Hospital Association made a canvass of automobile accident cases in that state and found that the hospital bills resulting therefrom amounted to \$810,489.14, and of this

amount 50 per cent proved uncollectible.

"In New Jersey a study of highway accident cases treated in nincteen hospitals showed a total of 1781 patients with 22,400 hospital days and bills amounting to \$106,089. Of this amount 56 per cent was collected and hope has been abandoned of any further collections on these accounts. It can be reasonably assumed that the percentage of loss to the physicians treating these cases was even greater than the losses to the hos-

"The St. Louis Safety Council has tabulated 7,732 accidents with 8,542 persons injured and 929 killed in Missouri in 1931. In St. Louis during the first eight months of 1932 ending August 31 there were 5,340 automobile accidents with 2,828 persons injured. The City Hospital treated 1,405 of the cases and 255 were treated in private hospitals. Of the 1,405 treated at the City Hospital 800 received only first aid and 605 were hospitalized. Of the 255 treated in private hospitals 78 received first aid only and 177 were hospitalized. Thus it will be noted that the City Hospital takes care of approximately four times the number that are treated in all private hospitals combined.

"The committee on economics of St. Louis concluded that legislation making the fees of a physi-

cian or hospital for services in such emergencies a lien on any money received as liability damages by the party responsible for the accident is the best means of protecting the physician and hospital and recommended the introduction of such a bill at the next session of the legislature."

A MEDICAL INSURANCE PLAN FOR CALIFORNIA

The November, 1932, issue of California and Western Medicine contains a description of action by the Council of the State Medical Association permitting county medical societies to undertake to give medical and hospital service on a periodic payment plan. The plan is essentially one of insurance for the payment of bill for medical attendance and hospitalization. It does not appear that the plan is in actual operation in any county. The report reads:

"The Council of the California Medical Association at its meeting held in Los Angeles, September 24, considered the report of the Committee on Public Relations, as presented by the chairman, whereby component county medical societies, by two-thirds majority of its membership, might adopt one of four suggested types of medical and hospital service on a periodic payment, plan

"The following principles were adopted which must be embodied in any approved plan undertaken by local societies:

"The plan shall include an insurance principle whereby the beneficiary pays at periodic intervals specified sums to be used for defraying the expense of his illness.

"Medical or hospital service shall be considered separately from indemnity for disability. The service in the beginning shall be limited to professional attendance only.

"The sole control of any organization for medical service must be limited to members of the profession.

the profession.
"Compensation for professional services—medical or surgical—shall be on the unit basis

"Professional service under any plan adopted shall be limited to the membership of a component county medical society or groups thereof endorsed through its official organization by two-thirds majority of its members. No plan shall be adopted or put into effect except with the approval and under the direction of the Department of Public Relations.

"The beneficiary member shall have the right to the selection of any physician or surgeon from

Scientific Control With Comfort in SCROTAL HERNIA

The usual irritation and possible injury from using a truss in scrotal hernia are avoided by this special belt support designed by S. H. Camp and Company (Model No 126). With the hernia reduced and a pad affixed and applied, it holds the intestine firmly in its proper place. Perineal straps, adjusted so they do not cut into the groin, prevent slipping. Pressure on the rupture is relieved with less tension, yet with all of the support necessary. This comfortable firmness engenders a feeling of both ease and confidence.

(Continued from rage 186-adv. xviii)

the entire membership of the county society or group thereof that participates in the plan.

"Medical and surgical service will be rendered by means of a copartnership composed of a fixed number of general partners selected by the component county medical society and the remaining members of the county medical society participating in the plan will act as assistants to or associates of the general partners. All services will be rendered on a unit basis. A tentative draft of copartnership agreement and contract for medical and surgical service has been prepared.

"The terms of this contract will prescribe and determine the injuries and illness covered, extent of service, etc. All Workmen's Compensation

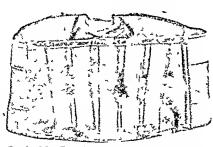

cases are excluded.

"Hospital service will be rendered by a corporation, incorporated under the laws of the State of California, for the purpose of furnishing and supplying beneficiary members with hospital and nursing service on a monthly payment plan through existing approved private hospitals.

"The corporation will consist of administrative and beneficiary members. Only members of the county medical society in good standing are eligible for administrative membership. "Beneficiary members will be those who meet the necessary qualifications, namely, that they shall have lived in the county months and shall have been engaged in a gainful occupation for a certain period of time. Their net income from such occupation shall not exceed a given amount, namely, \$2,000 a year. They shall have passed a physical examination by a designated administrative member. Beneficiary members will be liable for the payment of monthly dues in such amount, form and manner as may be determined and designated in the by-laws of the corporation.

"The County Mutual hospitals will have authority to provide and set up the necessary machinery to furnish the beneficiary member with approved hospital service, and to contract for said hospitalization with existing approved hospitals and to establish an administrative office for accepting applications from beneficiary members, receipts for monthly payments, actuarial and statistical departments, credit department, etc.

"No plan of organization for hospital service controlled by hospitals on a periodic payment plan has as yet been projected, but the committee it now at work on such a plan."

PRESS COMMENTS IN WISCONSIN

The comments of newspaper editors on the report of the Committee on the Costs of Medical Care often contain words of wisdom and philosophy which physicians may note with profit. The January issue of the Wisconsin Medical Journal quotes editorials from a number of the daily papers of the State. Discussing the economics of the report the Journal says:

"Back of it all, of course, there lies a fundamental economic problem. Many, many people cannot afford the medical care they need; at the same time many, many physicians are not making a living wage. This report seeks to find a very set of the

find a way out of these difficulties.

"But it is just possible that the real cure lies deeper than a more reorganization of the medical profession. The wage-earner's mability to pay for the care he needs, and the doctor's inability to get the income he deserves—aren't these a part of a larger problem whose solution depends on a restoration of economic health to the whole community?

"In the long run, what we need to aim at is a restoration of prosperity on a broader and firmer base than we have ever had it before

"Certain benefits from these medical centers are at once apparent. There would be a saming in costs to most families, especially those that may be hard hit by illness. There would be created an opportunity we have never had of making available to all patients the best treatment that science has disclosed. The correlation between public health service and private practice and the extension of public health service could be promoted.

"And yet, this proposal is based on some considerations that have not been proved. It is assumed that the individual relationship between the patient and the doctor of his choice could be preserved. Is that true? Could we still have the family physician relationship, confidence and faith? Also it is assumed that this socialization would not disturb the high quality of those entering the medical profession. Again, is that true?

"We have progressed too far in the extension of public health, industrial medicine, group medicine, to go back now. The demand for lowered costs is imperative and must be met. Also, we shall not be satisfied with a system that makes all of science available to some groups and not to others.

"The doctors can be helpful. Their view-point should be considered. Also, there should be further analysis of some of the assumptions pointed out above. But as a people who regard health as the most vital factor in their lives, we are not going back to the old way.

(Continued on page 189-adv. xri)

(Continued from page 188-adv. xx)

There is going to be progress along the line here proposed, or along some line that is pretty closely related to this proposal.

"Whether the American people get good medical care depends, in the last analysis, on whether they have sufficient good sense to

demand it.

'That seems to be the point of the latest report made by the Committee on Costs of Medical Care. The report points out that the nation is suffering from a shortage of competent doctors, dentists and hospital facilities: but it adds that it would be unwise to increase the supply until the general public knows enough to insist on first-rate attention and is willing to pay for it, as that would simply increase unemployment among medical practitioners.

"The problem, then, seems to depend on the patients themselves. Medical science can not. in the long run, serve them any better than they want to be served. They cannot get the best until they insist on it."

INDUSTRIAL CONTRACT PRACTICE IN WASHINGTON

The November issue of Northwest Medicine

contains the following account of industrial practice in the State of Washington.
"In 1917 Pierce County Industrial, Medical and Surgical Service Bureau was formed. The plan adopted permited any member in regular standing of the Society to join. Officers were elected and a manager was hired, who secured contracts with firms coming under the jurisdiction of the Department of Labor and Industries. The purpose of this organization was to take care of the injured workman, giving him the free choice of physician in contrast to the closed contract system. Supplemental health or sickness contracts were also written so that the workman would be covered for twenty-four hours of the day, including sickness or accident on or off the job. After fifteen years of existence this organization still continues to function. Many abuses have crept in, both from the physicians that render their services and the unsound cost arrangement.

"The cost of medical and surgical care has increased but the old dollar a month charge has continued. The present economic period has raised havoc with all classes and with all known standards. For the systematic study and attempted regulation of the present problems, our present organization, the Physicians and Dentists Business Bureau, came into existence a little over a year ago. Included under our Bureau are: (1) Nurses Exchange, (2) Doctors and Dentists Exchange, (3) Collection Bureau, (4) Branch Read-

MEAD'S 10 D COD LIVER OIL IS MADE FROM NEWFOUND-LAND OIL

Professors Drummond and Hilditch have recently confirmed that for high vitamins A and D potency, Newfoundland Cod Liver Oil is markedly superior to Norwegian, Scottish and Icelandic Oils.

They have also shown that vitamin A suffers considerable deterioration when stored in white glass bottles. For years, Mead's Cod Liver Oil has

been made from Newfoundland Oil. For years, it has been stored in brown bottles and light-proof cartons.

Mead's 10 D Cod Liver Oil also enjoys these advantages, plus the additional value of fortification with Mead's Viosterol to a 10 D potency. This ideal agent gives your patients both vitamins A and D without dosage directions to interfere with your personal instructions. For samples write Mead Johnson & Company, Evansville, Ind., U. S. A. Pioneers in Vitamin Research. See page xxx.—Adv.

RESEARCH STAFF-LILLY

Clinical observations on Merthiolate confirm the conclusions reached by the research staff of Eli Lilly and Company that this organomercury compound is an efficient bactericide in the pres-Physicians ence of organic matter. are quick to note other advantages: safety in therapeutic use, tissue compatibility, ability to stimulate cell regeneration and processes of repair, and the wide range of applicability of Merthiolate in all types of disinfect on and clinical antisepsis.

Another interesting feature of Merthiolate is its merit as a biological preservative. Lilly biologicals are reported to be sterilized and preserved by Merthiolate. Certain advantages are said to accrue to products thus treated. We are told that when Merthiolate is used in the preparation of bacterial vaccines, less change occurs in the antigenic qualities of the micro-organisms than when heat or other chemicals, such as cresol or phenol, are used.

Tests conducted at the Lilly Laboratories show less loss of potency in biologicals when Merthiolate is used as a preservative. Clinical reports indicate that injection of these products is not followed by stinging or pain. It would appear that Eli Lilly and Company have made another important contribution to medicine and surgery in the development of this germicidal agent. See page xii.—Adv.

READER

The onset of the winter season invariably is the precursor of such discases as Pneumonia, Bronchitis, Pleurisy, Tonsillitis, etc., the treatment of which requires a topical application of recognized merit.

The value of Antiphlogistine in the treatment of these conditions is standard therapeutic measure.

By supplying prolonged and uniform moist heat, and due to its osmotic, relaxant, decongestive and anodyne efficiency, Antiphlogistine checks the spread of the infection and enhances the natural powers of resistance. It is an essential remedy in the therapeutic armamentarium of the physician for the relief of inflammatory and congestive conditions, both deep-seated and superficial. Members of the medical profession are invited to write to The Denver Chemical Mfg. Co., 163 Varick

Street, New York, for sample and liferature. See page ii.-Adv.

VICHY CELESTINS

The American Agency of French Vichy, Inc., sole American agents of "Vichy Célestins" water bottled at the Spring at Vichy, France, owned by the French Government. There are other Springs at Vichy also owned by the French Government such as Grande Grille and Hopital which are imported by these Agents but these are not sent here in as large quantities as the "Vichy Célestins." This Agency also imports the tins." This Agency also imports the Vichy Salts and Vichy Pastilles which are called Products of Vichy-Etat because they are made from the Salts extracted from the waters of these government-owned Springs. Medical Profession of the United States annually sends many patients for the treatment of diseases of the stomach, liver, etc.—See page xix.—

ACUTE RUPTURED APPENDICITIS COMPLICATING CHRONIC LEUKÆMIC MYELOSIS

By BEN-HENRY ROSE, M D, NEW YORK, N Y.

PRECACE

OLLOWING the first description of Lenkamia in 1857 by Von Friedrich and the intense studies made in this disease by Virchow, interest in this blood dyscravia has attracted the attention of many observers who reported their cases in the various journals of the reported cases showed the classical symptom triad of a marked increase in the total number of white blood cells, an increase in the myeloeytic element, and the presence of a splenic en-largement or tumor, besides other interesting pathological findings Surgical complications of this disease have apparently never been reported and very rarely observed. It is for this reason that I am publishing in detail this most interesting and unusual case of ruptured appendicitis in a patient suffering from clironic leukaemic mi closis without palpable enlargement of the spleen, and who presented some extremely interesting blood studies

CASE HISTORY

H G, adult, female, white, widow, age 49, admitted to the Royal Hospital on October 25, 1931

CHIER COMPLAINT

Three days before admission to the hospital, the patient began to complain of slight cramplike pains over the whole of the abdomen unaccompanied by nausea or vomiting. Her bowels were made to move with enemata. Flirty hours prior to admission, the cramp like pains increased in severity and became localized in the right lower quadrant where they became markedly severe, still unaccompanied by nausea or vomiting, and unrelieved by enemata or icebag. The patient was able to move about in bed without any increase in pain. The temperature rose steadily to 101.5 F, and the pulse rate to 96

PAST HISTORY

Two years ago, the patient began to complain of bleeding from the mouth varying in amounts from a drop to staining a hundkerchief full. At

times it was pure liquid blood, at other times At no time was it caused by coughing, the bleeding seemed to come on spontaneously She complained of pain over the left cheek, and visited innumerable physicians, none of whom had taken a blood count during all this time X-Ray of the chest was repeatedly negative. She also complained of pain in and behind the left eyeball, and she was told that her trouble was due to a diseased left antrum Despite repeated treatments and washings by various nose and throat men, her bleeding and pain did not stop Several of the nose and throat men remarked on the spongy character of the wall of the antrum However, no attempt was made to explain it. The bleeding from the gums seemed to stop spontaneously six months ago. About two months ago, the patient went to a dentist who extracted several teeth in the upper left maxillary region, which was followed by a persistent purulent discharging sinus. A week previous to the present illness, the patient went to a dental surgeon who decided to curet the maxilla because of the discharging sinus, and open into the antrum he curetted, much spongy decayed grayish-white bone was extracted There seemed to be no limit to the amount of decayed material which he curetted He stopped the operation washed out the antral cavity and packed it with iodoform The patient began to ooze and since the bleeding did not stop the packing was removed and the gums sutured. Four days prior to admission, the patient began to bleed from the suture The bleeding was constant and the patient swallowed much blood and infected material. It became necessary to resuture the mucous membrane with dermal suture over a pressure pad to secure instant and complete hemastasis while she was actively bleeding from the sutured mucous membrane that the patient began to complain of cramp like pains in the abdomen

At no time did she have periods of diarrhea She was always constipated and resorted to laxatives and enemata for relief. She had never had a similar attack of abdominal pain before. Her appetite was always good. She did not lose any

weight, nor was there any progressive emanciation. She always had a mild degree of pallor to her skin. Urination was normal, and she did not complain of any dysuria or frequency.

Adult Medical: Bleeding from the mouth for two years. Occasional attacks of grippe.

Adult Surgical: Hysterectomy for fibroids of the uterus with hemorrhage, 1925. Operation for drainage of left antrum, 1931.

Menstrual History: 13x5x28 until 1924. Patient complained of menorrhagia and metrorrhagia; hysterectomy 1925.

Marital History: Married 31 years, 2 children, no abortions or miscarriages. She denied any venereal infection.

PHYSICAL EXAMINATION:

General Appearance: Adult, female, white, pasty color, not emaciated, apparently in pain.

Head: Normal size and shape. Eyes reacted equally to light and accommodation. No tenderness on pressure over the eyeballs.

Nose: Normal shape, no obstruction to breathing.

Left Antrum: Did not transilluminate as clearly as the right. There was some swelling over the left cheek as a result of the recent operation.

Mouth: All the teeth on the upper left side had been removed. The gums were sutured and showed no evidences of bleeding.

Tongue: Coated, small ulcerative patch on the left side.

Throat: Tonsils small, not diseased.

Neck: No cervical adenitis, thyroid normal.

Heart: Normal size, shape and rhythm. No adventitious murmurs heard.

Lungs: Normal vesicular resonance and nurmur.

Abdomen: The liver was palpable at the costal margin. The spleen was not enlarged nor was it palpable. The abdominal wall was well formed, somewhat flaccid, and showed evidence of a healed median hypogastric scar as a result of a previous operation. There was some rigidity and spasm of the lower right rectus muscle. As one passed one's hand lightly over the skin over the right lower quadrant, one could palpate a mass which was extremely tender to even slight palpa-This mass was easily movable, apparently saucer-shaped, and lie parallel to the fibers of the external oblique muscle. Elevation of the thigh on the abdomen without pressure did not increase the pain. With slight pressure over the right lower quadrant, pain and tenderness were greatly increased. Rebound tenderness was exquisite.

Vaginal Examination: Perineum relaxed; cervix small and smooth, forming a firm bed for the abdominal pelvic floor. There was no tenderness

in either fornix. Combined abdominal vaginal examination over the right lower quadrant was difficult because of the extreme tenderness on slight pressure over this region.

Glandular: There were no glands palpable in the cervical, axillary or inguinql regions.

Skin: Normal texture, pale color, no evidence of any petechiae or ecchymoses.

Mucous Membranes: No evidence of petechiae.

Operation: Under anesthesia, one could definitely see a mass protruding over the right lower quadrant midway between the anterior superior spine and the umbilicus. A McBurney intermuscular incision was made directly over this mass, the aponeurosis of the external oblique incised and muscles separated, and as the peritoneum was opened foul smelling colon pus was aspirated. The peritoneum was deeply hæmorrhagic in color. The abdominal cavity was walled off, the cæcum and appendix were delivered out of the wound, and the latter was gangrenous in its distal half, ruptured, and covered with plastic exudate. The mesentery, which was glistening and oedematous, was freed from the appendix and ligated. The appendix was divided between clamps applied closely to its base; its stump ligated, alcoholized and carbolized, not inverted but dropped back into the abdominal cavity. One tube was inserted down to the pelvis, and a cigarette drain to the stump of the appendix. An attempt was made to ligate all the bleeding points, but there was generalized oozing of very thin, almost watery blood from all the surfaces. The abdomen was closed in layers, using plain catgut No. 2 for the peritoneum and muscle, chromic catgut No. 2 for the fascia, and interrupted silk for the skin. The immediate postoperative condition was good.

PATHOLOGY:

The appendix was 6 c.m. x 1 c.m., and the lumen contained much free pus. It showed all the evidences of acute exudative inflammation with oedema and necrosis of the mucosa. There was no evidence of myelocytic infiltration.

LABORATORY FINDINGS:

Pre-operative Blood Count:

Hæmoglobin 75%; R.B.C. 3,720,000; W.B.C. 190,000; Lymphocytes 10%; Polys 85%; Eosinophiles 2%; Myelocytes 3%.

Postoperative Blood Counts:

10 hrs. Postoperative: Hæmoglobin 40%; R.B.C. 3,100,000; W.B.C. 96,000; Polys Segmented 91%; Young Forms 5%; Myelocytes 1%; Lymphocytes 3%.

20 hrs. Postoperative: (Dr. N. Rosenthal) Hæmoglobin 70%; W.B.C. 330,000; Polys Staff 18%; Polys Segmented 48.5%; Polys. Bas. .5%; Lymphocytes 2.5%; Monocytes 2%; Myclocytes Neut. 25.5%; Myeloblasts 3%.

30 hrs. Postoperative: (Dr. N. Rosenthal) Hæmoglobin 62%; R.B.C. 3,750,000; W.B.C. 220,000; Platelets 510,000; Polys Segmented 40%; Polys Staff 28%; Lymphoeytes 2%; Monocytes 3%: Myelocytes Neut. 27%.

6 Days Postoperative: Hæmoglobin 63%; R.B.C. 3,100,000; W.B.C. 140,800; Polys Segmented 61%; Band Forms 9%; Young Forms 2%; Lymphocytes 5%; Mononuclear and Transitional 1%; Eosinophiles 1%; Myelocytes 21%; Very few myeloblasts; Occasional normoblast, Mitotic cell, anisocytes, and Poikilocytes; Very few cells seen having morphology of myeloblasts and which give peroxidase reaction.

24 Days Postoperotive: IImmoglobin 68%; R.B.C. 3,350,000; W.B.C. 43,600; Polys Segmented 68%; Young Forms 1%; Band Forms 5%: Mononuclear and Transitional 1%; Lymphocytes 9%; Eosinophiles 2%; Basophiles 1%; Myelocytes 13%; Very few myeloblasts; Occasisonal Anisocyte, and Poikilocyte; Very few cells seen having morphology of myeloblasts giving positive peroxidase stain. (Negative for lymphoblasts.)

64 Days Postoperative: Hæmoglobin 74%; R.B.C. 3,648,000; W.B.C. 171,200; Polys Segmented Forms 58%; Band Forms 8%; Young Forms 1%; Large mononuclear & Transitional Forms 1%; Lymphocytes 11%; Eosinophiles 2%; Myelocytes 12%; Myeloblasts 8%; Occasional anisocytes and poikilocytes; Myeloblasts present giving positive peroxidase reaction (i.e. negative for lymphoblasts).

Pre-operative Urine: Pale amber; clear; acid; sp. gr. 1.007; very faint trace albumin; sugar, indican, acetone, diacetic acid, bile, crystals, amorphous and blood cells negative; occasional hyaline casts; very few squamus cells; occasional bacteria.

Pastaperative Urine:

4 Days Postoperative: Amber; turbid; acid; sp. gr. 1.010; Albumin ++; Urea 0.7%; sugar, indican, acetone, diacetic acid, bile, crystals, pus and blood cells negative; many urates; very many coarse granular casts; many epithelial cells.

15 Days Pastaperative: Examination revealed faint trace of Bence-Jones Albumin, 0.2%.

Postoperative Course:

The patient continued bleeding profusely from the wound directly after the operation and the wound dressing had to be reinforced several times during the night, despite the fact that icebag was applied directly over it. The patient retained retention enemas of 5% glucose in normal saline. The pulse rate rose to 128, and fifteen hours after the operation 300 c.e. of citrated

lilood was given intravenously. This was followed by a rise in temperature to 104.2, pulse 142, respirations 40, with a severe chill lasting fifteen minutes.

Consultation with Dr. Nathan Rosenthal (Hæmatologist): After examining the patient and before examining the blood smear, he did not lielieve the patient was a true case of leukæmia because of the absence of the large spleen, absence of petechia, etc., and thought that this was a case of thrombo-asthenia. After the blood examination, he changed his diagnosis and believed this to be a case of latent myeloid leukæmia.

On the following day, the patient felt somewhat better, and because she began to vomit small quantities of fluid, a Levine tube was passed through her nose into the stomach and gastric lavage was done with weak solutions of bicarbonate of soda. The vomiting stopped with this Forty-eight hours postoperatively, the patient began to bleed again through the wound. The pulse rate rose to 134 and was of very poor quality. Immediate blood transfusion of 250 c.e. of citrated blood was given, which was followed by a chill lasting twenty minutes and a temperature rise to 104.2, pulse 150, respirations After the chill, the pulse quality became stronger and dropped to 118, temperature to 101, respirations to 24. The following day, the Levine tube was again passed through the nose and the stomach lavaged to relieve the vomiting from which the patient suffered. The wound began to discharge a brownish-red foul smelling discharge which was probably disintegrated blood which was in the peritoneal cavity. On the fifth day postoperatively, it was necessary again to lavage the stomach through a Levine tube, and a transfusion of 450 citrated blood was again given. The patient reacted favorably after the chill which followed the transfusion. The temperature, pulse and respiration rates gradually diminished as the patient was in the hospital and the wound drained considerable greenish purulent discharge. cigarette and rubber tube drains were removed. The patient was in bed for twenty-three days, after which the discharge from the wound had sufficiently diminished to permit the patient to sit out of bed. At this time another blood examination was made which showed a marked diminution in the total number of white blood cells to 43,000, with the presence of 22% myelocytes. The Bence-Jones Albumin was 0.2%.

The patient was discharged from the hospital on November 23, her general condition greatly improved, with no bleeding from the gums, no petechiae, a normal sized spleen, and with the abdominal incision almost entirely healed. Dressings were continued at her home and the wound closed firmly and solidly within two weeks after her discharge from the hospital. After returning from the country six weeks later, the patient

gained some weight, felt well, her appetite was good, but she still complained of pain in and behind the left eye-ball due to a possible myeloma of the orbital wall. Palpation and percussion of the spleen revealed no enlargement of this organ. A blood study performed at this time, sixty-four days after the operation, revealed the presence of 171,200 white blood cells per c. mm., with 12% myelocytes and 8% myelocytes which gave a positive peroxidase reaction.

COMMENT

Myelogenous leukæmia is a disease of the reticulo-endothelial system, the chief organs to be affected being the spleen and the bone marrow, the exciting cause acting upon the reticulo-endothelial cells with the production of myelocytes and neutrophile leucocytes which pass into the blood in numerous numbers. It appears more frequently among the males than females, and manifests itself usually between twenty-five and forty years. The disease is usually chronic and of several years' duration, but the acute form is also described which runs its course in a few weeks.

The changes in the bone marrow would seem to be best described as a hyperplasia. The resemblance of leukæmia to an infectious process and the known action of chemotaxis in infectious leucocytosis suggest, as Reed has observed, that leukæmia is due to the action of some chemotactic agent or agents which by withdrawing certain varieties of leucocytes from the bone marrow cause a compensatory hyperplasia to replace the elements of the type withdrawn.

Merely a great increase in the white corpuscles is not necessarily characteristic of the specific disease, leukæmia, the diagnosis being dependent rather upon the presence of such special forms of cells as myelocytes. These reticulo-endothelial cells assume the property of the bone marrow as well as in manufacturing the granular series of leucocytes, and that in consequence, the spleen is one mass of leucocytes and polymorphonuclear leucocytes, which overflow and obliterate the Malphigian bodies and compress the blood sinuses. Similar appearances are seen in the liver and the bone marrow, the fat of the latter being replaced by a pinkish-gray mass of cells so formed that solid blocks can be cut out. The changes of the marrow and the liver are active, whereas an accumulation of myelocytes in the lymph glands is merely passive as these glands do not participate in the process.

A review of the various pathological reports of cases of myelogenous leukæmia reveals the leukæmic invasion of other organs besides the spleen and bone marrow. There is Warthin's case where the ileum was extensively involved in a large abdominal tumor which extended to the kidneys, stomach and regional lymphatic system, a careful study of this case demonstrating small hæmor-

rhages with pigmentation in all the serous membranes, mucosa of the intestines, bladder, eyegrounds, brain, bone, heart, lung, muscle and skin: the blood vessels were engorged with myelocytes; myeloblasts were demonstrated in groups outside the vessels; and some of the vessel walls were degenerated and myelocytes penetrated them. In Logefeil's case, the abdomen and intestines showed numerous petechial hæmorrhages in the serosa of the intestinal coils; and an intestinal polypoid mass was found in the cæcum-sections through this mass showed it to be due to an infiltration of leukæmic cells into the mucosa and necrosis was quite marked. Musser and Sailer reported the findings of irregularly punched-out and serpiginous ulcers in the lower portion of the ileum and throughout the whole extent of the large intestine including the rectum. reported by Simon and Rosenthal, the omentum was peppered with large and punctate hæmorrhages; the serous coverings of the viscera contained numerous petechiae, and the mesenterymore especially that of the small intestine-was diffusely hæmorrhagic; there was no free blood in the peritoneal cavity. Solomon reported the presence of blood in the lumen of the small intestines, in a pronounced case of splenomyclogenous leukæmia.

Cases of myelogenous leukæmia, in which, together with an improvement in the patient's general condition, there is a disappearance of the splenic tumor and at the same time of the myelocytes, are apparently very rare. The few instances recorded in the literature are those of McCrae, Senn, Plehn, and Simon and Campbell. In the latter's case, the classical features of the disease, viz., splenomegaly and myelemia, could be demonstrated and then disappeared twice within less than twelve months, and at neither intermission was there any evidence of an intercurrent disease to account for the improvement.

There are several interesting features in the The unexcase which I have reported here. plained pain over the left antrum and behind the left eyeball, the spongy character and grayish appearance of decayed bone of the antral wall, are undoubtedly caused by the myelocytic invasion of the bones comprising the walls of the antral and orbital cavities. How simple the explanation of the symptoms would have been had someone, during the two years in which the patient complained of bleeding from the mouth and pain over the left cheek and behind the eyeball, made a clinical blood study as a part of his examination of his patient. Indeed, she presented no other clinical features, viz: progressive weakness, loss of weight, emaciation, diarrhoea, petechiae and no splenic tumor. If it were not for the development of an attack of appendicitis-she might have gone on unrecognized for some time! The influence of the suppurative process on the blood is evidenced by the preponderance of polymorphonuclear leucocytes in the preoperative and first postoperative blood-sniear examinations; the true nature of the blood dyscrazia showed itself in the third blood-sniear taken twenty hours after the operation. As the purulent infection was on the ascendency, evidenced by the increasing purulent secretion from the abdominal cavity, the total number of white blood cells increased in amount to 330,000, and with the subsidence of the infection—decreased to 42,000, although the number of myelocytes remained approximately the same. At no time during the infection or after her discharge had the spleen increased in size.

A resume of the history of this patient with a copy of the blood studies were sent to Dr. A. Piney, Haematologist to the Cancer Hospital of London. He agrees with me that this case is a genuine example of chronic lenkaemic nyelosis of the chronic type. The fact that the total number of leucocytes has subsequently increased to 171,200 per c. mm., with many immature forms, seems definite evidence. The presence of Bence-Jones protein is unusual and is, as a rule, a grave sign, but in the present case may be incidental to the infection and not of great importance in prognosis.

THE DIAGNOSIS OF PULMONARY NEOPLASMS

By HENRY MONROE MOSES, M.D., BROOKLYN, N. Y. From the Medical Service, Kings County Hospital, Brooklyn, N. Y.

TUDY of the history of medicine by an individual is usually begun a few years after having been graduated from a medical college; and the question sometimes arises in one's mind as to whether or not the recent graduate in medicine realizes fully the comparatively recent advances in the methods of diagnosis, and the advantages which he has over those of the earlier practitioner in medicine. This fact is well illustrated in the methods now used in the diagnosis of pulmonary neoplasms.

An example of the difficulties of diagnosis of a pulmonary new growth is found in the report of a patient under the care of Dr. Robert J. Graves, of Dublin, one hundred years ago. We find in his lectures on clinical medicine, an excellent, detailed history, physical findings, course of the disease and gross post-mortem findings, upon a patient having a pulmonary

tumor. A study of this history will be of benefit to one who might care to review it. The comments of this keen clinician in reference to this patient are of historical interest; he states at the beginning of his lecture:

"Rare diseases should not be looked upon as mere matters of curiosity but should be attentively studied with the view of enabling us to recognize the true nature of similar cases when they again occur. The diagnosis of encephaloid tumors of the lungs was, a few years ago, completely impossible; but I trust that ere long we may be enabled to arrive at some degree of certainty even in this difficult and obscure branch of thoracic pathology. The wish to promote so desirable an object has induced me to publish the details of the following case, chiefly valuable on account of the accuracy with which the symptoms were observed during life."

After giving the history and post-mortem findings, he concludes:

"Such are the most important particulars of this remarkable case, which, during the patient's life proved an opprobrium to the science of diagnosis, for it is scarcely necessary to observe, that both myself and colleague, Dr. Stokes, were completely mistaken as to its nature. Aneurysm; circumscribed pleuritic effusion, and enlargement of the heart; pleuropneumonia; pleurisy and hepatization, in consequence of previous pneumonia; solidification from tubercles, etc. were each successively advocated: as to myself, I became quite tired of the difficulty of attempting to explain the phenomena observed, with any of the diseases I had originally fixed on as the causes of the symptoms; and latterly, however erroneously positively I had been when I first took the man under my care, I gave up all further attempts at diagnosis; and yet it seems strange that the external tumors did not awaken a suspicion of the true nature of the case, for although we were not permitted to examine them, their nature was certainly the same with the internal. At the present stage of our investigations on this subject it is premature to attempt pointing out true features, which may hereafter serve for making the correct diagnosis in similar cases; some of these features are sufficiently obvious, but we must wait for additional facts before the symptoms peculiar to this disease can be pointed out with accuracy."

These expressions of doubt by this able observer, present, with the greatest force, the paucity of knowledge of these pulmonary tumors one hundred years ago, compared with our knowledge at the present time,

The method of making a diagnosis at the present time is exemplified in the following histories:

Case 1.—A male, thirty-nine years old, was admitted to Kings County Hospital complaining of a cough of nine months' duration, which was at first dry but later productive, with hemoptysis on three occasions; weakness became so marked that he had not worked for six months; there was marked loss of weight; for eleven weeks before admission to the hospital, the pain had been so severe in the right lower chest that the patient had been in bed this length of time. In addition, his family physician had made a diagnosis of tuberculosis of the right upper lobe.

Physical examination on admission gave evidence of a mass in the right upper lobe, and there were signs of a cavity in the right lower lobe. Frequent examinations of the sputum for the tubercle bacillus were negative. His

blood Wassermann was negative. The next steps in diagnosis were the fluoroscopic examination and the Roentgen-ray picture which showed a localized area of tumor in the right upper lobe, and an abscess cavity in the right lower lobe.

Following this, a bronchoscopic examination was made from which a diagnosis was given as carcinoma of the bronchus with secondary retained abscess cavity. A biopsy specimen of the bronchial tumor was obtained; the microscopic report upon the specimen is as follows:

"This section shows neoplasm composed exclusively of squamous epithelia arranged in rather disorderly manner. There is definite pearl formation and areas of keratinization. There are attempts at tumor giant cell formation. Diagnosis; squamous cell carcinoma."

This patient died thirty-seven days after admission, and no post-mortem examination was permitted.

When we consider that secondary tumors metastasize to the parenchyma of the lung, and not to that part of the bronchus observable through the bronchoscope; also that primary carcinoma in the lung originates in the bronchial tree; and that when a biopsy specimen is obtainable through the bronchoscope, we have a primary carcinoma of the bronchus, we must consider this patient as having a primary pulmonary neoplasm.

Case 2.—The following history is of interest as the ante-mortem diagnosis was confirmed by post-mortem examination. A man, forty-six years old. was admitted to Kings County Hospital complaining of severe, paroxysmal pain in the right upper chest, of seven weeks' duration; he had a cough productive of a whitish sputum which had been blood-tinged on two occasions; he had lost twenty-five pounds in weight in six weeks; anorexia had been present since the onset of pain; he complained of dyspnea on exertion, and was cyanosed. Physical examination led us to believe that he had a new growth in the right upper lobe, and the methods followed in the patient reported above were followed with this patient. died nineteen days after admission. The postmortem findings confirmed our diagnosis of primary carcinoma of the lung.

In making a diagnosis one hundred years ago. Graves had the history, the physical findings. the course of the disease and the gross findings of the tumor at autopsy, as the use of the microscope was not general at this time.

To these findings have been added:

(1) the fluoroscopic examination and the Roentgen-ray picture;

(2) the bronchoscopic examination and the microscopic examination of the specimen obtained during life;

(3) the histological findings at autopsy.

A study by the writer of 140 patients with pulmonary neoplasms, primary and secondary shows the following different types of tumors:

13 primary carcinoma of the lung, with autopsy findings.

51 carcinoma of the lung, believed to be primary, without autopsy reports.

44 carcinoma of the lung, secondary to carcinoma elsewhere.

20 lymphosarcoma of the lung, secondary.

8 sarcoma of the lung, secondary.

3 hypernephroma of the lung, secondary.

1 teratoma of the lung, secondary.

The primary carcinomas of the lung, with autopsy findings have been reported in detail.2, 2, 4

The greater number of primary carcinoma of the lung are reported as originating in the bronchus, one writer on the subject making the statement that all primary lung tumors are broneliogenic. These primary carcinoma are accessible to the bronchoscope and a biopsy specimen may be obtained except in cases of sub-mucous growths, which may extend into the parenchyma. Primary growths in the bronchi may metastasize into the parenchyma and cause general diffuse carcinoma or carcinomatosis throughout both lungs. When a biopsy specimen can be obtained, and is histologically proven to be carcinoma, one may safely assume that the patient has a primary carcinoma of the lung, since secondary growths attack the parenehyma, the pleura, or the mediastinal lymph nodes, and not that part of the bronchi which is accessible to the bronchoscope.

Primary sarcomas of the lung have never been satisfactorily proven. Lympho-sarcoma of the lung are never primary. Secondary carcinoma in the lung are more apt to be diffuse and spread throughout both lungs causing carcinomatosis, although occasionally discrete nodules are formed, this occurs more frequently when metastasizing from the breast. Secondary sarcoma usually appear as discrete

nodules, spherical in shape, which vary in size. Secondary lymphosarcoma, forming discrete nodules, appear chiefly at the hilus and spread out from there. Hypernephroma metastases may appear as discrete nodules but usually form one or two large spherical tumors, larger than sarcoma and fewer in number. These tumors are sometimes called the "cannon ball" tumor of lypernephroma. Chorioma may metastasize as discrete spheres about the size of a golf ball.

Roentgenologically the appearance of primary carcinoma of the lung depends upon the stage of the disease, and its progress. In the earlier stage picture, there are signs of diminished aeration, beginning atelectasis and obstruction; later the growth appears in the lung field directly, and still later, we find signs of pneumonitis, destruction and cavity. The appearance of these tumors, primary and secondary, are usually grouped into four classes:

- (1) The nodular type.
- (2) The infiltrative type.
- (3) The lobar type.
- (4) The lymphogenic type.

The appearance of a tumor in the fluoroscope or in the rocutgenological picture indicates an advanced state of malignancy, whether primary or secondary, for which little benefit has been possible, as yet, by treatment. Earlier methods of diagnosis must be found, and in order to make an earlier diagnosis in primary carcinoma of the lung, the bronchoscopists are advocating earlier examination by the bronchoscope in all cases of persistent cough without known reason, or any condition which seems due to irritation, such as wheezing. The use of the bronchoscope will undoubtedly be the means of earlier diagnosis in cases of primary carcinoma of the lung.

By the time secondary tumors appear in the lung, the entire system is involved with malignancy, and attempts at relief must be directed not only to the lung condition but also toward the primary growth.

The recent developments in methods of diagnosis of pulmonary neoplasms have been shown in contrast to the methods used one hundred years ago.

DIABETIC DIETS

By ARTHUR H. TERRY, JR., M.D., NEW YORK, N. Y.

From the Medical Service, Beekman Street Hospital, New York.

HERE are several diabetic forms and systems, each one easy for the originator but difficult for others. Probably the simplest and most universally used form is by Dr. Joslin. The one here proposed, as devised for the Beekman Street Hospital, is more or less patterned from it. The difference in this from is that the first four diets are for special conditions, namely: what to give when the patient has mild acidosis or a fever, or when requiring soft food, as after an operation; or what a child needs. No diet is provided for real coma, as none is possible.

The special diets are listed according to name and according to their carbohydrate, protein, and fat content. This content is measured in grams of food; and on the reverse side of the card the gram measures are given in household measures for those unable to use a gram scale.

The last six diets are employed for the routine treatment of diabetics entering the office; each succeeding diet increasing in carbohydrate, protein, and fat content. A diet sufficiently high in food must be given to make the patient happy and to maintain body weight and strength. Sufficient insulin must be given, before each meal if necessary, to keep the urine sugar-free. It may be possible to get along with insulin before breakfast and supper or merely before breakfast. On the other hand, an additional small dose on retiring may be necessary.

Diet number eight is the best average diet; and about ten units of insulin before breakfast and supper are usually required to render the urine sugar-free morning and evening; five units more or less, probably sufficing to keep the afternoon urine sugar-free. Frequent small doses of insulin are usually more effective than one or two large doses.

TABLE 3. Food Values.

LIPOID HISTIOCYTOSIS CASE REPORT

By A TOW, MD and H F WECHSLER, MD, NEW YORK, N Y

erom the A Jacobi Division for Children, Service of Dr J S Leopold, and the Achelis Laboratory, Dr C F Rohdenburg Director Lenox H II Hospital New York City

C INCE Pick established the disease as a clinical entity, examples of lipoid histocytosis have been published with increasing frequency and with clinical and pathological descriptions that are almost monotonous in their similarity However, the disease is still rare enough to be recorded, and especially our case because it occurred in an infant of pure Italian stock. We have been able to find only three cases of lipoid histocytosis reported in non Jewish patients-two of German and one of French parentage Again, the discovery of the resemblance between the findings in the brain in this condition and those in amairrotic family idiocy has, in recent years necessitated a complete revision of our conception of the idiotic form of the disease. It has become evident that there exists a fundamental relationship between the two, and that in all probability the same metabolic dis turbance is the etiological factor in both. In some instances it affects primarily the visceral organs. and in others the central nervous system

CASE REPORT

MC, female age nme months, of pure Italian parentage on both sides, was admitted to the A Jacobi Division for children, Lenox Hill Hos pital on July 15th with the diagnosis of acute intoxication

The family history was negative except for the fact that the father and mother were first cousins Two children were living and well and three had died, two during the first week of life with signs of intestinal obstruction and one at six months of pneumonia

The patient was a full term normal delivery with a birth weight of seven pounds. Breast milk and various formulae had been given but the in fant had failed to gain weight and develop nor-A marked respiratory stridor had been present since birth. At the age of six months adenectomy had been performed in an unsuc cessful attempt to relieve the stridor For two days prior to admission, there had been intractable vomiting and diarrhoea

Physical examination revealed a poorly developed, acutely ill female infant; weight 10 pounds 3 ounces. A diffuse papular folliculitis was present over the back. The palatal arch was high and the tonsils were greatly enlarged. The liver was palpable three fingers beneath the costal arch in the nipple line and the spleen extended almost to the umbilicus.

The patient was given a transfusion of 80cc. of whole blood but grew steadily worse, and expired six hours after admission with signs of acute intoxication and edema of the lungs.

Autopsy:

The body was that of an emaciated, poorly developed infant, 9 months of age and measured 63 cm. in length. The skin was of a dirty grayishbrown color. A papular rash was present on the forehead, shoulders and back. The frontal bosses were prominent and the anterior fontanelle was open.

Both lungs lay free in the pleural cavity. The right lung weighed 125 gms. and the left 75 gms. They were light purplish-pink in color, felt firm and fleshy and the interlobular markings stood out clearly as a grayish yellow network. On section, they had a mottled appearance, solid dark red and yellowish areas alternating with pink, crepitant ones. The network visible over the pleural surface extended throughout the lobes.

The larynx and trachea showed no gross abnormalities.

The tracheobronchial lymphnodes were enlarged, firm and yellowish-brown in color.

The thymus was grossly negative.

The heart weighed 35 gms. and except for a pale, flabby myocardium revealed no abnormalities.

The liver was markedly enlarged, weighing 400 gins. The right lobe extended into the right iliac fossa. Its surface was light yellowish-brown in color and was doughy in consistency. On section it had a grayish-yellow, boiled appearance and the markings were completely obliterated.

The spleen was of huge size, weighing 185 gms. It was of a mottled red and yellow color and the Malpighian corpuscles were apparently much re-

duced in number.

The pancreas felt somewhat firmer than normal but was otherwise negative.

The adrenals were firm and on section, the medulia was of a yellowish-pink color.

The kidneys together weighed 50 gms. and revealed no gross abnormalities.

The stomach was dilated and contained a large amount of mucus.

The solitary follicles and Peyer's patches of the

small intestine were markedly enlarged and were vellowish-pink in color. A few scattered enlarged follicles were present in the colon.

The abdominal lymph nodes were enlarged, firm

and mottled reddish-yellow in color.

The brain was small and rubbery in consistency. The meninges were dull gray in color, the convolutions normal and the sulci widened.

Microscopically, the characteristic picture of lipoid histiocytosis was present. The hyperplastic reticuloendothelial cells stained a faint orange with Suda iii, pinkish-red with Scharlach 4, a light grayish-black with osmic acid, bluish-black with the method of Lorrain-Dittrich and with Mallory's stain the nucleus was reddish-brown and the cytoplasm a light pink.

These cells practically filled the sinuses of the spleen and markedly encroached upon the Malpighian corpuscles. Many of the latter had disappeared entirely, others showed small collections of lymphoid cells interspersed among the endothelial cells. The pulp, where visible, contained a few scattered round cells, an occasional poly and a small number of red blood cells.

In the liver they filled the sinuses and compressed the liver cells. The latter showed marked degenerative changes and extreme vacuolization. Small collections of polys were occasionally pres-

ent about the degenerating liver cells.

In the lymph nodes the architecture was completely altered by the cells and the lymphoid elements were much reduced in number. medulla of the adrenal and the thymus contained them in great abundance. They were extremely numerous in the lungs, in many areas completely filling the alveolar spaces and to a lesser extent were found in the septa and about the bronchi and blood vessels. Serous fluid was present in some alveoli and hemorrhage had taken place into others. A few small foci were present in the kidneys. The epithelium of the convoluted tubules exhibited marked degenerative changes and in many areas were completely necrotic. The blood vessels were congested and a few small hemorrhages were present in the interstitial tissue between the tubules. The lymph follicles and Peyer's patches showed moderate numbers of these cells. The stomach, pancreas and heart muscle were negative.

The brain showed a diffuse vacuolar degeneration of the cells, most marked in the cortex of the cerebrum and cerebellum. The cells were enlarged, the nuclei were eccentric and the cytoplasm was foamy in appearance. cells were especially abundant about the blood vessels. The ganglion cells in addition showed granules which took the hematoxylin, absence of Nissal bodies and displacement of the cell processes.

THE PRESENT STATUS OF THE ALLERGIC DISEASES*

By T. WOOD CLARKE, M.D., UTICA, N. Y.

THREE years ago I presented a paper before the Oncida County Medical Society and the Pediatric Section of the State Society analyzing twelve years' experience in the study of allergic diseases in childhood. Since then I have extended this work to adults referred to me by my fellow physicians.

The present paper is not confined to the pediatric aspect of the subject but gives a summary of the present-day status of our knowledge of the allergic diseases referring to my own work only by way of presenting illustrative cases.

Theobald Smith's discovery of anaphylaxis in guinea pigs in 1904, von Pirquet's introduction of the term allergy, Meltzer's suggestion that bronchial asthma was a manifestation of anaphylaxis in 1910, and Schloss's introduction of skin testing in 1912 form the foundation on which is built our knowledge of the allergic diseases.

Allergy may be defined as a hypersensitiveness of body cells to one or more specific proteins. When such a protein, called an állergen, comes in contact with the sensitized cell, morbid conditions occur which cause symptoms complexes grouped together as allergic diseases.

ETIOLOGY

Heredity plays an enormous part in allergy. From forty to sixty per cent of all patients suffering from allergic diseases give a family history of allergy in some form.

The hypersensitiveness to protein itself is not inherited, but the capacity to become hypersensitive is, and this follows the Mendelian law as a dominant characteristic. With this inherited background, the actual hypersensitiveness is due to antibody formation by the action of foreign protein upon the cells of the patient.

A sensitized guinea pig can pass its sensitization to its offspring in utero, and when a pregnant guinea pig is given horse serum hypodermically, the embryo becomes sensitized. Thus intro-uterine sensitization may be either passive or active. In some cases where young infants are allergic to a certain food, the mother is found to have had an inordinate appetite for the especial food stuff during her pregnancy. This explains the advent of allergic symptoms following the first ingestion of the offending protein by the infant.

Schloss¹⁰ demonstrated that while unchanged proteins cannot be absorbed into the blood through the normal bowel wall, they will pass through the mucosa during intestinal disease.

Hypersensitiveness, therefore, is due to excessive doses of some protein, either in utero, in the ordinary course of existence, or from abnormal absorption through intestinal lesions.

When once the specific hypersensitiveness has been established, it remains but for the specific protein or allergen to which the cell is sensitized to come in contact therewith when a colloidal shock occurs, and symptoms of one of the allergic diseases results.¹¹

The allergens which are the exciting cause of this shock may be the proteins of foods, of pollens, of clothing, of bacteria, of animal eminations as hair, dander, or feathers, or of smoke, powders, dust, or numerous other substances. Symptoms indistinguishable from allergic shock can also be produced by non-protein drugs and chemicals.

Talbot,¹² O'Keefe,¹³ Shannon,¹⁴ and Lyon¹⁵ demonstrated that a nursing infant might receive allergic shock hy means of allergens included in the mother's diet and transmitted to her child through her breast milk. Balyeat¹⁶ and Sterling¹⁷ present evidence that a similar condition exists in regard to cow's milk.

One case of maternal transmission is worthy of reporting:

Case J. P., 4½-months-old child, nursed every 3 hours. For the past two months he had severe eczema covering face, body, arms and legs. Skin tests by the scratch method made a dozen at a sitting over a period of several weeks gave reactions to rice, banana, chicken, egg white and yolk, veal, tomato, and cat hair. The foods were eliminated from the mother's eliet and ultraviolet ray was used locally. The improvement was very slight. On the last day of testing reactions were obtained to several nuts. The mother then stated that as the family physician had prohibited candy owing to the baby's cezema, she had been eating nuts in considerable quantities. Elimination of the nuts from the mother's diet caused complete disappearance of the eczema in two weeks.

PATHOLOGY

When the allergen comes in contact with the antibody which appears to be located in the globulin fraction of the serum and cells, 18 certain pathological changes occur characterized by spasm of smooth muscle, stimulation of glands, and increased permeability of the capillaries. 10 There is an eosinophilia in the blood and in the secretions from the respiratory tract.

These lesions, spasm and oedema, may occur at the point of contact or at widely disseminated parts of the body, and may so produce widely different symptoms.

Read before the Fifth District Branch of the Medical Society of the State of New York, at Oneida, N. Y., October 4, 1932.

GENERAL MANIFESTATIONS

The manifestations of allergy involving the entire body may be acute or chronic. The acute symptoms make the syndrome known as allergic shock exemplified by acute serum shock with which all are familiar. Such symptoms may follow the introduction of the foreign protein by mouth, or by hypodermic injection.

In other cases the ingestion of the foreign protein may produce high fever as illustrated by the

following case.

P. M., born September 19, 1928, at Lowville. At the end of one week it was given complemental feedings of cow's milk, and at the end of the second week was weaned. He promptly developed a crowing respiration and fever, and was admitted to St. Elizabeth Hospital at the age of 3 weeks. The child was found to be so allergic to cow's milk that the slightest amount thereof would cause a fever of 104° to 105°. During six months in the hospital, five attempts were made Each attempt was followed by to give milk. croupy respiration and high fever. Upon removing milk entirely and giving soy bean, barley and olive oil (a mixture subsequently introduced by Hill20 and given the name of Sobee) and banana cream, the child throve well.

The chronic general manifestation of allergy comprises what Rowe²¹ and Kahn²² have described as allergic toxæmia. It is due to the chronic ingestion of foods or the inhaling of pollens to which the patient is allergic and produces symptoms of general malaise, nervous irritability or melancholia. With removal of the

allergens prompt recovery ensues.

SKIN INVOLVEMENT

The most common of the manifestations of allergy, especially in children, are those involving the skin.

In eczema there are two factors, an allergic background and a local irritant. Both factors are necessary to produce the lesions in the skin. This explains the marked improvement by the local use of ointments, x-ray and ultraviolet rays, and the prompt return of the symptoms when these methods of treatment are discontinued.

The allergic sensitivity producing eczema is usually due to the ingestion by mouth of food proteins, the most common causes being egg, milk, or wheat. Orange, so commonly accused of being the causative factor, has in my experience

been very rarely a cause of eczema.

Besides foods, articles of bedding or clothing may produce eczema, an especially common cause being silk. Many children are having their clothing lined with silk to protect the skin from the irritation of wool, when wool is quite harmless and silk a violent poison.¹

· While allergic hypersensitiveness is not the only factor in eczema, it is certainly the most im-

portant one, and the attempt to treat the disease by relieving the local irritation alone by ointments and ray treatments and neglecting the allergic aspect, is but doing half the job and striving for temporary relief instead of permanent cure.

In one group may be considered the conditions characterized by itching and local swelling of the skin, pruritus, urticaria, giant urticaria and angioneurotic oedema. Wynn²³ has reported two severe cases of general senile pruritus lasting for months, which gave reactions to wheat globulin, were relieved when all wheat was removed from the diet, and relapsed promptly after the ingestion of even one slice of bread.

Urticaria and angioneurotic oedema have been known for years to be intimately associated with the ingestion of certain foods. They may also be caused by bacterial allergens arising from points of focal infection in teeth, tonsils, or sinuses.²⁴ Menagh²⁵ reports finding biliary tract infection in 48% of a series of cases of urticaria and angioneurotic oedema, and obtained excellent results from the administration of autogenous vaccine. Urticaria has been produced by the allergic reaction to the malarial parasite²⁶ and to trichophyton in "athletes foot."²⁷

The bizarre nature of the etiological factor in urticaria is well illustrated by the case of a young woman who had suffered for six months from daily distressing attacks of hives. Series of skin tests failed to give positive reactions. months later she wrote me that she had discovered the cause of her hives. Since the onset of her trouble, on the theory that it was due to indigestion and that pepsin chewing gum was good for her digestion, she had conscientiously chewed gum for a short time after each meal. Two months before writing me she had gone on a camping trip and forgotten to take her gum. To her astonishment she had no hives. then she has chewed no gum and had no signs of urticaria.

It long has been known that some individuals will develop an acute dermatitis upon coming in contact with certain substances quite harmless to other persons. The best known example of this is poison ivy.²⁸ Some people cannot wear collars made of certain furs without having acute inflammation of the neck. Henna and other hair dyes, commonly harmless, may cause acute distress in people allergic thereto.

Dermititis, too, may recur every spring in those sensitive to timothy²⁹ and every autumn in the person with a ragweed allergy.^{30, 31} The skin of florists may show acute hypersensitization to such irritants as the leaves of chrysanthemums³² or that of a housekeeper to the pyrethrum of insect powders.³³ The acute dermatitides occasionally following the injection of arspenamine are of a similar nature.³⁴ Even ephedrin, a drug of such value in the treatment of all forms of

allergy, may at times defeat its own ends by sensitizing the patient and producing a dermatitis 85

RESPIRATORY MANIFESTATIONS

Asthma

The most characteristic and commonly recognized of the respiratory manifestations of allergy are asthma and hay fever. Three theories are held as to the nature of asthma that it is a spasm of the smooth muscle of the bronchial wall, that it is an ocdenia of the mucosa, and that it is a plugging of the bronchi due to hypersecretion of the bronchial mucosus glands 36. It is probable that they occur simultaneously, as all three are types of lesions characteristic of allergic shock.

While foods may be the cause of asthma, more commonly the paroxysm is precipitated by some substance inhaled from the air. Horse, dog and cat asthma have been known long before the theory of allergy was propounded asthma, especially following years of suffering from hay fever, is a common occurrence. Among the other frequently met excitants of asthma may be mentioned silk, orris root found in sachets and face powder, pyrethrum, or the basis of most of the insect powders, and glue of the last of the support of the saction of the insect powders, and glue of the last of the support of the last of the saction of the insect powders, and glue of the last of the last of the saction of the sacti

A few years ago a child was sent to me with eczenia and asthma, who proved to be sensitive to horse and eattle hair, a number of foods and Some months later the boy was ill with a non-related condition. He had two mirses One he would allow at the bedside, the second Upon the latter administering he objected to to lum, his respiration rose from thirty to muety with no rise in temperature The boy's condition was unchanged except for the astonishing increase in respiratory rate Careful questioning revealed that nurse number two was wearing silk bloomers These being removed, the child's respiration rapidly returned to normal, and his objection to the nurse vanished

Probably the most common factors in the production of asthma are the contents of pillows Chicken, duck and goose feathers, Kapok or cottonsced¹⁰ may precipitate an attack, and where they come on suddenly in the middle of the night they are the usual cause. Parrott¹⁰ and canary¹¹ feathers have been found to be the cause especially among bird fanciers. In New York City rabbit hair¹⁴ raiks high as a cause of asthma due to the custom of certain New York pillow makers of mixing rabbit hair with the feathers in their pillows and of the use of felt pillows.

The most common of the foods causing asthma are eggs wheat milk, and the condiments especially mustard 42

Recently a young man was seen who had been a chronic sufferer from asthma for 21 years As his attacks always started with what his mother considered to be a cold and as she feared that the cold would run into asthma, she did all in

het power to break up the cold. Her regular routine was flax-seed tea and hot ministard foot boths. In spite of all her efforts, however, the colds always developed into asthmatic attacks. A study of the case revealed that the two substances to which the pritient was most sensitive were ministard and flax-seed. He was instructed to discontinue his treatment of colds and at the last report was free of his asthma.

Recent studies lead to the belief that the emanation of certain insects as said flies, moths, or butterflies⁴⁴ may produce the disease. The literature is full of case reports of asthma produced by the most bizarie and unexpected causes as Christmas trees,⁴⁵ maple leaves⁴⁶ human dander,⁴⁷ bowood,⁴⁸ and such drugs as ipecac⁴⁹ and the easter oil bean ⁴⁰

To add to the difficulty in solving the problem of asthma is the fact that in the majority of cases there are many varied and entirely unrelated allergens

Hay Fever

Seasonal hay fever, or pollenosis, is one of the commonest of diseases. It is estimated that one per cent of all human beings suffer from it in one form or another 31. Its allergie inture, its dependence upon tree pollens in the early spring, upon grasses in Jime, and upon weeds, especially ragweed in August, are too well known factors to require more than passing comment. Amy pollen which is wind disseminated may be a cause of hay fever. The insect germinated pollens, as rose and goldenrod, can cause them only if the sensitized patient comes in intimate contact with the flowers.

In seasonal hay fever one should not be content with determining the nature of the pollen scusitization, but should investigate also the possibility of an allergic reaction to foods, animal emanations and other allergens, for it has recently been abundantly demonstrated that a patient who is pollen sensitive but cannot be cirred of the hay fever by the ordinary methods of treatment will respond promptly if some food to which he is sensitive is at the same time removed from the diet or if contact with animals feathers or orris root is discontinued ⁹²

Closely related to seasonal hay fever is the symptom complex known to the allergist as perennial hay fever, and to the rhinologist as vaso motor rhuntis

The sufferers from this disease show all the symptonic common to seasonal pollen hay fever except that these occur throughout the year, either constantly or in repeated attacks with sudden onset and equally sudden relief. On examination of the nasal mucous membrane it is found to be swollen grayish in color and glistening in appearance. The nasal secretion is profuse and watery. It contains large numbers of cosino plules. The clinical picture differs distinctly from

the red turgid mucous membrane, and the mucopurulent or purulent discharge of infections.⁵³

Many of the cases of chronic running noses, obstructed breathing, mistakenly diagnosed as sinus disease and operated upon therefor, are really allergic in character. In such cases often repeated operations of tapping of sinuses, removal of turbinates and snaring of polypi have been performed with little or no relief.

While sometimes occurring in patients suffering from seasonal hay fever or asthma, perennial hay fever may appear as an independent affection due, either to foods or to inhalants. As an example of the variegated etiological factors in this condition, the last five cases which have been referred to me for investigation by a rhinologist have proved to have an allergic hypersensitiveness to wheat, to pyrethrum from insect powder, to cat hair and parrot feathers, to cheese and the pneumococcus and to tobacco respectively.

If the practitioners, and especially the rhinologists had a more widespread appreciation of the allergic nature of many of the chronic incurable nasal conditions which they treat palliatively year in and year out, there would be less unsuccessful nasal surgery and a great decrease in the sniffling population.

Besides the running of the nose these cases are characterized by lachrymation, sneezing, especially in the morning, and itching of eyes, nose and ears.

Allergic croup⁵⁴ may be of any degree of severity. Probably many of the mild cases of spasmatic croup in childhood are due to allergic sensitiveness of the child, either to foods or more probably to the feathers of the pillows. As these croups are either due to muscle spasm or to oedema, the two characteristic lesions of allergy, it does not take a great stretch of the imagination to include them in the allergic category. This probability is emphasized by the fact that the usual cause of death in allergic and anaphylactic shock is suffocation due to spasm and oedema of the larynx, in reality the same condition which occurs in a milder form, in nocturnal spasmatic croup.

Cough is not infrequently an allergic manifestation either associated with hay fever or asthma, or as an independent affection stimulating recurrent bronchitis. The cough may be associated with a running nose, and may precede an attack of typical asthma, giving rise to the mistaken notion that the asthma is caused by "catching cold." The coryza and cough are not due to infection but are as much a part of the allergic attack as is the wheezing of the later stages of the attack.

Colmes⁵⁶ has reported a case of uncomplicated recurrent cough due to orris root, and Rackeman and Colmes⁵⁷ have presented a series of

similar cases caused by orris root, animal hairs and feathers. A case reported by me¹ several years ago bears repeating. The child had frequent attacks of bronchitis, blamed by his mother on becoming overheated due to over-exertion when visiting his grandmother's house in the country. On my obtaining a reaction to cat hair, his mother denied this possibility as in their apartment house life they saw no cats. The child interruped by saying that at Grandma's there were stray cats in the barn and he always had fun catching them. He stopped catching cats, and during the past fourteen years has had no bronchitis except last year when a new cook in the family brought a cat into the house.

Balyeat⁵⁸ goes one step further than bronchitis and describes what he calls pseudo-bronchopneumonia. He pictures the "patient who develops an acute cough with dyspnoea, temperature, and lassitude. On physical examination these children may have a temperature of 99° to 104° and the other findings will not differ from the true bronchopneumonia. Within 12 to 36 hours the condition has cleared up. The child is perfectly normal, running and playing and apparently no worse for the attack of bronchopneumonia." He believes that these cases are allergic and urges that where there is a history of repeated attacks of bronchopneumonia and a family history of allergy, the allergic etiology be given serious consideration.

OPHTHALMIC MANIFESTATIONS

The allergic nature of primary diseases of the eye has received but slight attention. Individual reports of cases of vernal conjunctivitis.⁵⁹ scleritis,²⁰ recurrent retinal oedema,⁶⁰ and episcleritis⁶¹ of allergic origin and cured by the removal of the offending allergens have been reported. These cases suggest that the oculist by keeping allergy in mind may increase his percentage of successes in certain troublesome eye conditions.

GASTRO-INTESTINAL MANIFESTATIONS

The digestive manifestations of allergy are caused by ingested food, and may be due to a direct contact reaction of the protein upon the mucosa, or as a part of a general reacton after the protein has been absorbed. The intensity of these reactions may well be understood when one considers the intimate relation of the allergen to the sensitized wall of the digestive tract.

Cases of recurrent canker sores in the mouth due to such foods as chocolate, wheat. or cabbage, in which complete relief was obtained by removal of the offending foodstuffs from the diet, are known.63

Since Osler's⁶⁴ classical article calling attention to the abdominal crises occurring in the erythema group of diseases, several surgeons

have described finding at operation swellings of the intestinal wall resembling angioneurotic oedema and characterized by intense thickening with little or no involvement of the lining mem brane Careful study by many allergists have led to the belief that these conditions are evidences of food allergy In Rowe'ses analysis of 150 cases of gastro intestinal allergy, he describes canker sores, conted tongue, and heavy breath, distention, belching, epigastric heaviness sour stomach and burning, nauser vonuting, diarrhoca, and many other symptoms including pain and tenderness in any and all parts of the abdomen and The duration even acute intestinal obstruction of the symptoms in his series varied from four months to fifty-five years

The most dramatic manifestatious of gastromtestand allergy have been recognized for many years under the title of food poisoning. In these cases it has been known that certain foods were poisons in children especially egg and the ingestion of even a small amount of the substance may produce swelling of the hips and tongue, oedema of the glottis intense comiting, sometimes

dyspnoer, collipse, and even death

It is possible that many of the cases of chronic indigestion in which the physician cannot satisfy himself of the presence of any organic lesion are due to the oedema and muscle spasm caused by local allergic reactions in the intestine

Where the symptoms follow the enting of sonic uncommon food as erali, lobster, or strawberries, the recognition of the relationship between the food and the symptoms is simple. When the allergen is one of the common foods duly eaten is wheat, eggs, or milk no connection is appreciated but study of the problem has shown that it is just these three common foods which are most prone to produce the symptoms of gistro intestinal allergy. Exerman has demonstrated by x ray examination of the colon the spastic condition of that organ after the administration of wheat to a sufferer from wheat allergy.

Lintz⁶⁷ has shown that in a large percentage of cases of asthma a careful examination of the gastric contents and the stools reveals the presence of blood, and he believes that this is due to concomitant swelling of the gastro intestinal mucosa due to the allergic process

Owing to the acuteness of the abdominal cramps and the tenderness over the oedematous gut produced by areas of local allergie reaction in the bowel the diagnosis of appendicitis cholecystitis and gastric and duodenal uleer have been made in allergic cases and operations have been performed which were unundicated and failed to afford the patient the slightest relief. No allergist pretends that all cases of acute abdominal pain are allergic but they do point out that some of them certainly are and they urge the practitioner and especially the surgeon to

give this aspect of medicine more consideration in those eases in which the symptoms are not ac companied by characteristic physical signs of organic lesions, and especially in those unfor tunites who return some months after the removal of an appendix or a gall bladder with the cheering news that the symptoms are as bad as

Several years ago I was called to see the child of a Utica physician who had been under my care for asthma due to dog hair. At this time she was having intense abdominal pain and vomit ing. In the left hypochondrium there was a hard tender mass the size of a good-sized apple believed this to be a feeal impaction and ordered In twenty four hours the mass had disappeared A month liter, although the bowels had been kept well open the same thing was re peated and at irregular intervals since similar attacks have occurred always following the ingestion of egg, even in such small quantities as oceur in a piece of cake Although when first tested for her asthma the child gave a negative egg test, today the test for egg white is positive Undoubtedly this phantom tumor is a local allergic oedema of a portion of the intestine

Some allergists have gone farther than to say that allergy may be mistaken for acute abdominal lesions and believe that certain well recognized abdominal lesions of doubtful ctiology may

actually be of allergic origin

Schloss⁶⁸ has called attention to the resemblance of cyclic voniting to the recognized allergic discases, and reported a few cases in which the distressing condition was proven to have an allergic foundation. Others have noted similar

At times attacks of allergic vomiting are so reute that intestinal obstruction may be suspected. In one case, an infant of 13 months of age was referred to me whose constant vomiting and collapse for three days caused the family physician to make a diagnosis of intussusception. Lack of blood in the stools negative r ray findings and a sudden outbreak of hives put us on the right track. Milk allergy was demonstrated and the child which on admission appeared moribund on being given a milk free diet recovered immediately and gained eight ounces in weight during its week in the hospital

Cohen and Breitbartee have reported a series of cases of infantile pylorospasm in which they were able to demonstrate an allergic sinsitivity to egg milk, or cereals. They believe that these cases are allergic in character that the obstructive cases are sensitized in early intrainterine life and that repeated allergic shocks occurring during prenatal life cause the secondary hypertrophic After birth the child develops normally until it receives a dose of the specific allergem when spasm and oedema cause the distressing symptoms. The simple pylorospasm cases without

organic obstructions, according to their theory, are cases of late intrauterine sensitization and antenatal allergic shock. The theory is certainly interesting and explains many features of this distressing affection of early infancy.

Lintz⁶⁷ in his article on canker sores suggested that if allergic lesions could produce ulceration in the mouth, it might be possible that they would do the same thing in the stomach and duodenum.

Ivy and Shapiro⁷⁰ have reported successful production of gastric ulcers in the rabbit and dogs by first sensitizing the animals to a foreign protein and then later injecting a small quantity of the same protein into the gastric mucosa.

Last year Kern and Stewart 11 studied a series of 32 unselected cases of duodenal ulcer. In 40% of these there was a personal history of other allergic conditions, and in 60% positive skin tests were obtained to proteins, in 25% suspicious reactions and in only 15% negative reactions. several of the cases in which positive tests were obtained, clinical symptoms of ulcer could be produced by feeding the specific protein, and periods of complete relief could be obtained by eliminating all reacting proteins from the diet. While acknowledging that their series is too small for definite conclusions the authors believe that "evidence has been presented which tends to show that food hypersensitiveness may be an etiological factor in a small but appreciable percentage of cases of duodenal ulcer.

In 1922 Vaughan⁷² called attention to the fact that the characteristic symptoms of mucous colitis, smooth muscle spasm, and secretion of mucus were identical with those of asthma, and suggested the possibility that mucous colitis was an allergic disease. In 1927 Hollander⁷³ and in 1928 Vaughan⁷⁴ reported cases of typical mucous colitis of long standing in which it was proven that the patients were allergic to various proteins, and complete recovery followed their elimination from the diet. Immediate recurrence followed reingestion of the offending foods. Treated in the usual way mucous colitis is the bête noir of the physician. Studied from an allergic viewpoint, many cases show prompt and complete recovery.

NERVOUS MANIFESTATIONS

In 1922 Shannon⁷⁵ reported a series of cases of nervous, irritable children, some associated with eczema, asthma, or vomiting, and others with no such concomitant symptoms, all of whom were proved to have allergic susceptibility to foods. The nervous symptoms and instable temperament promptly cleared up when the offending material was removed from the diet, and returned upon its again being administered.

In 1919 Pagniez. Vallery-Radot and Nast⁷⁶ in an article in the *Presse Medicale*, called attention to the facts that migraine was a hereditary

disease, beginning in childhood and lasting for many years, coming on in sudden attacks without any evident etiological factor or else after the ingestion of some specific food. They further noted that it was often associated with attacks of asthma, urticaria, or gastro-intestinal disturbances, and they came to the conclusion that it was of allergic origin. Allergists since have been investigating migraine from the allergic viewpoint with such success that last year Balyeat⁷⁷ reported 202 consecutive cases of migraine, every one of which showed an allergic skin reaction. Of these cases the elimination of the offending proteins caused complete relief in 21% of the cases, good results in 37%, and fair results in 28%. In but 12% was there no benefit. When one considers the utter hopelessness of our efforts to relieve and prevent most migraine attacks by the usual methods, such a report certainly holds out hope for the millions who, through weary years, are doomed every few days or weeks to the agony and intense illness of this symptom com-

In 1921 Welchsler⁷⁸ in writing on epilepsy expressed the belief that the ingestion of certain foodstuffs bears a special relation to some cases of epilepsy. In the same year Thomson⁷⁹ of London in investigating 200 cases of convulsions in infancy laid special stress on the poisoning of milk, eggs, and cereals as the cause of con-The next year Wardso suggested the allergic nature of epilepsy and reported two cases in which positive skin tests were obtained and withdrawal of the offending food caused relief from the attacks. In 1923 Wallis and Nicol⁸¹ in England reported the study of 122 insanc epileptics among whom 46 gave skin reactions to proteins, while among 100 control non-epileptic insane patients only four reacted. VanLeuwen and Leydner⁸² extracted a substance from the blood of patients with asthma, urticaria, migraine, and epilepsy which, when injected into normal animals, produced muscle contractions. Howell83 then reported a series of cases of epilepsy sensitive to both foods and bacterens. Ward and Patterson⁸⁴ reported a thousand cases from the Craig Colony and the New Jersey State Village for Epileptics in whom 37% gave positive skin tests and 100 controls in which only 4% were positive. Spangler⁸⁵ reports 100 epileptics in 80% of which there was a family history of allergy. Waldbott⁸⁶ has recently reported two cases of epilepsy in which the attacks alternated with attacks of asthma.

While the allergic nature of all cases of idiopathic epilepsy is not proven and probably does not exist, there is strong evidence that at least a certain proportion of them are allergic and are curable. In a disease the outlook of which is so poor, one should grasp at any straw which holds out hope of curing even a small percentage of epileptics.

Last year I had a case of this kind. The patient, M. F., aged 10 years, was referred to me for convulsions. Her family history was negative. Her personal history miniportant except that she had had attacks of asthma since infancy and for the past four years had had typical epileptic convulsions of progressively increasing frequency until they occurred once or twice a week. Dermal tests gave reactions to cottonseed, cattle hair, radish, and cheese. Cheese and radish were eliminated from the diet, cotton was removed from her environment, and as she could not avoid the cinanations of cattle, inoculations with cattle hair were started.

As the dose of cattle hair increased, the frequency of the convulsions diminished until in the fall of 1931 they stopped entirely, and the child has now been quite free from both con-

vulsions and asthma for a year.

Other less frequently reported symptoms due to allergic involvement of the central nervous system are Meniere's Disease first described by Duke⁸⁷ and since confirmed by Rowe,⁸⁸ and certain transient cases of paralysis, hyperaesthesia, and local anaesthesia.

When one considers the tremendous local swellings which can occur on the surface in angioneurotic oedema or giant urticaria, it is easy to understand how similar acute swellings occurring in the cranial cavity could cause neurological symptoms of all kinds and description. The application of allergy to neurology opens a field of fascinating possibilities.

JOINT INVOLVEMENTS

There is probably no affection which causes more prolonged and intense suffering and a greater amount of disability than the group described under the heading of arthritis. When we have eliminated tuberculosis, gonococcus, syphilis, and acute infective joints from the category, we still have a large group of which the etiology is unknown.

Very little has been done towards studying these acute and chronic joints from an allergic viewpoint, although it has been recognized for many years that acute swelling of the joints is not an uncommon symptom of scrum disease after the administration of antitoxin, and recently orthopedists have been blanning certain acute joint swellings upon auto-intoxication.

Eight years ago Turnbull*o called attention to the fact that diet had always been considered an important factor in the production and control of arthritis. He then suggested the possibility of an allergic reaction in the synovial membranes. He obtained positive skin tests with various protein in a series of cases of arthritis in some of which there was associated mucous colitis. On removal of the offending foods, not only did the colitis improve, but the arthritis disappeared as

well. Failure to adhere to the diet caused imme-

diate return of the joint pain. Freiberg in 1929 reported an interesting study carried out on the theory that arthritis was an allergie reaction to a bacterial allergen. proved that an experimental arthritis simulating the proliferating arthritis of man could be produced in rabbits by sensitization to a bacteren, and then injection of a bacterial extract. next year Freiherg and Dorst91 reported an extensive series of clinical cases of arthritis which they studied by making cultures from all possible points of focal infection and from the stools. Individual vaccines were made with each organism grown. Skin tests were then made with these vaccines and those giving reactions were combined into one vaccine, and minute desensitizing doses administered. Their results were truly startling. In a series of thirteen cases with a duration varying from 18 months to 14 years they report seven cured, three with marked improvement, one with improvement, and only two with no benefit.

Last April Vaughan⁹² reported 100 cases of arthritis in which follow-up work had been done. He also considered the condition to be allergic and had treated with minute desensitizing doses of autogenous or stock vaccines. He, however, did not follow Freiberg's method of checking up his vaccines with skin tests. Nevertheless of his 100 cases, 10 per cent were completely relieved of their symptoms, 37 per cent were very much improved, 25 per cent were benefited somewhat, and only 27 per cent were not effected.

Miller and Lewines report one of the rare cases of intermittent hydrarthrosis of sixteen years standing completely eured by treatment on the theory that it was an allergic disease.

These few studies would seem to suggest that at least some cases of arthritis are of an allergic nature, and in a condition so long standing and resistant to therapy, it is possible that allergic studies may hold out some hope for the sufferer.

GENITO-URINARY SYMPTOMS

Irritable bladder⁹⁴, encuresis⁹⁶, and uterine cramps⁹⁶ have been described as allergic symptoms in isolated instances.

DIAGNOSIS

In the diagnosis of the allergic diseases, three things must be determined, first the clinical identity of the disease, second whether it is of allergic origin, and third the identity of the allergen which is the immediate cause of the attacks.

The first is answered by clinical examination and usually the symptoms are so characteristic that little difficulty is experienced.

The second, whether the manifestations are allergic or not, can usually be determined fairly

well by a careful history. The family history is of importance, as in most cases allergic manifestations occur in near relatives. A patient with asthma may have a mother with migraine, an uncle with urticaria, a sister with eczema, and a brother with hay fever. Such a family history strongly suggests allergy. In the personal history one must learn whether the patient suffered previously from allergic manifestations of any nature. An important item is to learn the patient's likes and dislikes, and whether any special food has ever upset him, or is consistently refused, for nature tries to protect the allergic subject from its specific poison by giving it a distaste therefor. Any child that expresses a distinct dislike for a food should have his allergic reaction to that food studied before he is forced to eat it.

The third matter to be decided is the nature of the specific allergen. This is done by the well known tests: dermal, intradermal, ophthalmic,⁹⁷ nasal,^{98, 99} patch,¹⁰⁰ and passive transfer.¹⁰¹

The dermal test consists of making a series of small abrasions on the patient's skin, and placing on each a minute quantity of one of the proteins being tested and dissolving it in sodium hydrate. The intradermal test resembles the Schick test in that the test material is introduced into the skin with a fine hypodermic needle. A positive reaction occurs in twenty minutes and consists in an irregularly shaped wheal in the center of an area of erythema. These are the tests commonly used, the other methods being reserved for special occasions where the dermal tests are unsatisfactory.

After Schloss' introduction of skin testing, his enthusiastic followers were of the opinion that all allergic diseases could be diagnosed by this simple method. It was, however, soon found that this was not true, and that a certain percentage of cases, typically allergic, failed to give skin reactions to proteins to which clinically they were susceptible. It is now found that nearly all seasonal hay fever cases give satisfactory reactions. Most asthmas and eczemas do likewise provided an adequate number of test materials are used. The gastro-intestinal allergies, the perennial hay fever cases, and the epilepsies give a moderate number of positive results, while the urticarias and the migraines are prone to be disappointing.

When all skin tests to specific proteins are negative, results may be obtained by testing with extracts made from the dust of the patient's house or with bacteria, yeasts and molds.

Various reasons have been given for the failure of the skin tests in certain cases. In allergy the susceptibility of different parts of the body varies, the same allergen in one patient causing asthma, in another migraine, and in a third urticaria. It is therefore easy to appreciate that a patient's nasal mucous membrane or meninges may be highly hypersensitive to a certain protein,

while the skin might have such a high resistance thereto that no positive test reaction could be obtained.

For a period directly following an allergic attack the patient develops a resistance to the exciting protein, not only in the part effected, but in the skin as well. This explains the periodicity of attacks and the presence of a negative skin test to a specific protein for a few days after an acute attack caused by that particular protein. For this reason tests should not be made immediately after an attack as at that time they are prone to give false information. When a patient has been free from contact with the offending allergen for some time the skin sensitiveness may be lost. The same thing happens after desensitizing treatment or after drug therapy. An inert allergen, owing to improper extraction or to age, may also lead one astray.

Not only may skin tests not be obtained in cases of definite allergy, but it is also possible for the skin to give positive reactions to substances, the administration of which cause no clinical symptoms.

This uncertainty of the skin test has led to the allergic theory and the testing methods falling into a certain amount of disrepute in some quarters, a disrepute justified if one is to depend upon skin testing entirely for a diagnosis. The skin tests are but one means of diagnosis, and are of value only when combined with the history of the case and the careful study of clinical symptoms, living relations, and dietary reactions.

A new stimulus was added to the study of allergy in 1928 when Rowe¹⁰² introduced his method of "elimination diets" in the diagnosis of allergy, especially in those cases giving negative tests.

On the theory that most food allergy cases were due to sensitiveness to eggs, wheat, and milk. Rowe devised a series of four fundamental diets in none of which do these substances appear. A patient suffering from symptoms of allergy is placed upon one or other of these diets. If symptoms continue, another diet is used until one is found that gives relief. If all diets are symptom-free they may be combined. The patient thus being on a diet causing no symptoms, one food at a time is added until symptoms appear. In this way the allergic nature of the disease can be determined and the offending protein identified even in the presence of negative skin tests. It is, however, always advisable to do a complete series of skin tests before attempting the elimination diets, as the information so received directs the choice and modification of a diet and may save one many months of tedious diet manipula-Vaughan¹⁰³ and Waters¹⁰⁴ have modified and elaborated these tests.

It will thus be seen that the accepted view of

the study of a case of allergy today includes a careful family and personal history, a complete set of skin tests, and then with the knowledge so obtained as sign posts, a careful dietary and environmental study of each case from a clinical standpoint. The diagnosis of a case of allergy has gone far beyond the mere scratching of the skin, applying proteins, and watching for the resulting wheal

TREATMENT

The first essential in the treatment of allergy is an accurate diagnosis, not only a diagnosis of the allergic nature of the disease, but also an identification of the offending allergens. In most cases several widely differing allergens are at fault and the failure of the identification of any one will vitiate the value of the treatment.

Once the allergens are recognized the first step is to eliminate the offending materials from the patient's diet or environment. If this can be done it not only gives relief from symptoms, but in some cases the allergic hypersensitiveness will disappear, and the patient will be permanently cured. Relapses, however, may occur either due to reappearance of the hypersensitiveness to the same allergen, or the development of allergy to a new protein previously innocuous

If the elimination is not possible owing to one's mode of life or to the fact that the food is so common that it cannot be avoided, or if the hypersensitiveness does not disappear, the next step is desensitization. This is carried out by the administration of minute quantities of the offending material by mouth in the case of a food, or hypodermically in the ease of bacteria or inhalants, these doses being gradually increased over a period of months until the hypersensitiveness is lost and the patient can take the normal amount of the material without symptoms secret of success in such desensitizations is con-The more slowly the dose of allergen is increased, the more successful the results. One overdose can cause immediate recurrence of symptoms

The moculation method is most widely used in the case of hay fever, and is if properly carned out, usually successful. If a case comes in during the hay fever season the coseasonal method may be tried, but too much should not be expected therefrom. The usual method is to begin some four months before the onset of the season and give weekly injections so that the immunity becomes well established when the pollen first blows Care must be used in the case of multiple reactions to use the pollens which are really causing the symptoms In 1927 Vander Veer, Cook, and Spain105 suggested that in order to prevent recurrence of hay fever in subsequent years, the inoculation be not stopped at the end of the season, but be kept up at monthly intervals during the entire year Vaughan, 106 Stewart, 107 and others have reported most favorable results by this method, more permanent cures being attained than by the purely seasonal treatment

Time will not admit of discussing the nonallergic treatment of the allergic diseases or the care of acute attacks, but it must be remembered that these cases need local and general medical treatment for their symptoms and the physician who depends entirely upon allergic desensitization is but doing hilf of his work

The inoculation of allergic cases with nonspecific proteins, using typhoid vaccines, sera, milk and peptones have had their advocates, but have not been generally accepted as comparing favorably with the specific treatment

Conclusion

The present status of the allergic diseases would seem to be that practically all cases of urticaria, angioneurotic oedema, seasonal hay fever, and most of the cases of uncomplicated astlma must be included in that category, that most cases of eczema not caused by direct irritatin or inflammation of the skin are allergic, that many cases of chronic rhinitis and recurring bronchitis are of a similar nature, that probably most cases of unicous colitis, and some cases of indefinite gastro intestinal symptoms including pain, natisea, and tenderness are due to allergic The suggestion has been made that pylorospasm and gastric and doudenal ulcer may have an allergic origin In the nervous system migraine is commonly caused by allergy Meniere's Disease may be another manifestation of the same condition and there is a probability that certain cases of epilepsy are of a similar nature Certain acute arthritides and some cases of chrome arthritis are probably allergic

If one runs his mind over this list it will be seen that most of them have in the past been clussed as diseases of unknown citology, not amenable to treatment Sufferers therefrom were doomed to lives of pain or discomfort and were of the type that drifted from physician to physician in the vain search for health

The allergist does not claim that he can work nuracles. He cannot cure all chronic incurables, but he certainly can cure certain cases previously considered incurable. The allergist does not ask that every case of bronchitis or abdominal pain be put through a course of skin tests, but he does ask that cases of asthma, eczema, uritcaria and hay fever be given this opportunity of relief, that, where migraine has gone on for years, after eye strain, constipation, and pituitary involvement have been eliminated, that where chromic indigestion has made hie miserable, and medical aid has been unavailing, that where a running nose persists in spite of the best local

medical and surgical care, and that where a child shows signs of beginning epilepsy without evident cause, the family physician offer this patient the chance of relief offered by an appreciation of the possible allergic nature of these diseases, and refer them to the allergist for careful study. If he does this, not all cases will be cured, but if successful results are obtained in even a small percentage of these supposed incurables, his patients will rise up and call him blessed.

SPEECH DISORDERS AS A MEDICAL PROBLEM* By SMILEY BLANTON, M.D., NEW YORK, N. Y.

31, 1931.

CPEECH is the highest function of the human organism. It includes not only words but the accompanying tones and bodily actions. It is one of the best indicators of whether the nervous system, the brain especially, is developing normally. It shows also injuries of the brain whether caused by trauma or disease, for speech, being the latest and highest function of the nervous system is very unstable and usually is affected by slight injury of the highest cortical cells.

Defects of speech due to organic injuries of the nervous system are seen in myasthenia gravis. where the speech difficulty very often shows itself first in a nasality due to a weakness of the soft palate. The scanning speech defect, in multiple sclerosis, due to a spastic incoordination of the tongue and vocal cords, is well known to all neurologists. In the majority of cases of general paresis we find a well marked speech defect characterized by a tremulousness of the voice and a slurring indistinctness of the speech, caused chiefly by an incoordination of the front part of the tongue, giving rise to distortion of the sounds, and a substitution of one sound for the other. The dysarthrias occur very commonly after brain hemorrhage, and the inability to understand language or to use spoken language, which is seen in the aphasias, needs no discussion here. Rather, I should like to emphasize the fact that in the dysarthrias, and especially in the aphasias, much can be done by careful, conscientious, skillful and persistent treatment.

In motor aphasia is treatment especially effective. It consists in the formation of new speech patterns by having the patient see the word, hear the word, write the word and try to reproduce the word vocally. If there is difficulty in saying the word, the exact posi-

tion of the tongue for the sounds in the word can be given. At first the aphasic should be given only words of one syllable and very common everyday words. Thorndike in his word book has made a list of the most used words in the English language. We select nouns from this list and start practice with these. There are, moreover, some twenty simple words which make use of all of the vocal positions called into action in making the fifty odd -ounds used in the English language. These words are:

yellow	plate
jacks	ĺiouse
tootlı	glove
pig	foot
ring	bird
letter	ball
shoe	white
nose	boy
knife	cap
lieel	mân
watch	

In the aphasic where the intelligence has not been seriously injured and where there is no paralysis of the peripheral speech organs, one can usually develop a large working vocabulary through training over a period of six months to a year. Care must be taken with the aphasic that he not be made tired and it is therefore better to have a practice period only a few minutes long at first with several periods dur-ing the day. Later the period can be lengthened to thirty minutes twice or three times a day.

A very frequent speech defect in children is found in Little's disease. Along with the spastic condition of the legs and the athetoid movements of the hands, there is a real inactivity and incoordination of the speech organs. Such children usually have suffered an injury

^{*} Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

of the basal ganglia which gives rise to incoordinated movements of the hands and legs but in many cases the intelligence has not been seriously affected, sometimes not at all. The speech, however, is very often marked by gross inactivity of the articulatory organs, especially the tongue, giving rise to slurring, indistinct speech which most people interpret as coming from a feebleminded or defective individual.

In the speech clinic at the University of Wisconsin some years ago we saw a boy who was in his junior year at college—he had been transferred from another college—who possessed a very brilliant mind but his speech was so defective that he found himself unable to engage in the social life of the college and as a result he had developed morbid feelings of shame and inferiority. He was twenty-one years of age at the time but two years of careful training so improved the boy's speech that he was able to speak without any serious defect.

Another similar case was that of a high school graduate who had specialized in the installation of electrical apparatus but who was unable to get a position because of his peculiar speech.

A third type of case was that of a boy of twelve who had had a rather severe hemorrhage at birth due to a difficult labor, whose legs were so spastic that he could only get about with difficulty, who still had athetoid movements of the hands, but whose intelligence quotient was 110. He had been placed in the hands of a speech trainer with more energy than insight who used to give the boy vocal training for two to three hours a day. As a result of this training the speech muscles were fatigued and less efficient and the speech became very much worse.

It is obvious, of course, that speech training in such cases must be given in very small doses and suited to the individual. Speech training for short periods was carried on for four years with this boy and at the end of that time his speech approximated the normal.

Another interesting type of speech difficulty was that of a little girl of three who came to the speech clinic ten years ago. At that time she was diagnosed as feeble-minded. She drooled at the mouth, made only a few animal-like sounds, her legs were quite spastic and there were marked athetoid movements of the hands. Observation of the child showed that she had a good deal of intelligence which was concealed from the casual observer by her serious injuries. Muscle training in general was prescribed and very short periods each day were devoted to games in which were some of the simpler speech sounds. The mother was so interested in the child's welfare that she

took a course in phonetics and speech correction and has carried out the training consistently and intelligently for ten years. At the present time the child's speech is almost normal. Her intelligence quotient is 105 and she is in the seventh grade in school. Certainly without speech and muscle training this child would not have been able to have developed her potential intellectual capacities.

We hope these cases show that much can be done, even when there is a serious injury of the nervous system, to bring back normal speech. The physician, however, should carefully supervise the speech training and thus avoid the possibility of over-training.

Perhaps the commonest speech difficulty that the physician meets with is lack of speech. The normal child begins to use words by the time he is 15 to 18 months of age. By the time he is two years of age, he should be using simple sentences, and by the time he is two and a half to three years the child of average intelligence should have a vocabulary of several hundred words and the child of superior intelligence who is developing normally should have a vocabulary of a thousand words or more.

It may be said safely then that the child who does not talk, that is, use at least single words, by the time he is two or two and a half years of age is suffering from a speech defect. The most common cause for children not talking at the right time is amentia, caused by a lack of brain development, the most common cause being defective genes. Occasionally it may be due to minute hemorrhages at birth, giving rise to no paralysis but injuring the higher cortical cells, or to encephalitis which blights the cells that underlie speech and leaves the motor system intact.

These amentia cases are often quite puzzling. The following case will illustrate this:

Patient is a boy four years of age. mother and father are both college graduates. intelligent and healthy. There are two other children besides this boy, a girl twelve and a boy ten, both of superior intelligence. The patient began to use a few simple words when he was 15 to 18 months of age—"mama," "go," "up." At the age of four years he has about 20 words which he uses. He uses only single words and has never put words together in even the simplest sentences. His hearing is normal, his body is perfectly formed, and he has very good coordination in balancing himself, in climbing, but shows some incoordinations when he tries to run. His hand coordinations are quite superior. He can take pegs out of a peg board and put them back in with a fair degree of skill. He does not control his bladder and if he were not taken

to the toilet four or five times a day would soil himself. His attention is very fixed. He will sit and put pegs into a peg board for an hour at a time and not be distracted by other toys or what other children are doing around him. This is a very ominous symptom in children. The normal child of four is much interested in his environment and does not fix his attention on one thing for long at a time. This boy is not interested in anything you say to him nor is he interested in his environment. He pays no attention to pietures, does not know the various colors, nor does he try to name the simple toys with which he plays. Every effort has been made to make him talk. The mother once withheld food from him for a whole day to make him say "juice" or "dinner" but without results. The family feel if the child would only talk that he would be quite normal but the fact is if the child were normal he would talk. He is very definitely feebleminded, probably a high grade imbecile, although the parents have not accepted this faet and are still going from doctor to doctor seeking help.

In this case I am sure that there is a lack of development of the higher cortical cells which underlie the function of speech. It is probable that this child will never be able to use anything but single words and probably his mental age will never be more than that of

a 4 year old child.

Another puzzling type of speech defect oceurs in children who have some intellectual retardation but a retardation in speech far greater than we should expect from the mental retardation alone. Such a ease is that of a boy ten years of age who, judged from his general behavior and from the Pintner-Patterson Performance Test, has an intelligence quotient of 83. He did not talk until the age of four. His speech is slurring and indistinct, he can not do first grade reading work and uses single words, rarely putting two words together.

I think we are justified in a case of this type of hereditary amentia in saying that we have a specialized defect of the speech area. Such children should be given speech training whenever possible for without speech training they will not be able to make use of the intelligence which they have. Good speech in such cases spells the difference between the person who will be economically dependent and socially inadequate and a person who may be taught to do some simple work and who can be trained to adjust himself to group living.

The child who has defective speech because of deafness requires teachers who have specialized in the training of deaf children. maintain that these children who are delayed in their speech because of defective hearing should receive speech training as early as possible. Where the parents can afford it, we urge them to place the child in a school where he can be given speech training daily.

The organic defect which remains after an operation for eleft hard or soft palate should be mentioned. If the soft palate can be used at all, rather fair results can be accomplished for the throat muscles are able to compensate and even a short soft palate with the help of the throat muscles can block off the back of the nose and fairly good speech can be ob-A ease which came to the speech elinie some time ago was that of Margaret, a child ten years of age, who had from birth a defective soft palate which although not cleft was very short. She has average intelligence but she is doing very poor work in school. She has developed a great sensitiveness about her speech defect, she does not like to play with other children, she cries very easily and is developing a quite morbid emotional attitude because of her speech defect. Training for six months has improved her speech materially and has also changed to a certain extent her feeling of inadequacy and inferiority.

There is a type of speech defect which we describe by the term "oral inactivity." This defect is characterized by an indistinctness and slurring of speech such as might be seen in a drunken man or in general paresis, or in the very markedly retarded child. We find such defects, however, in children who have superior intelligence. The defect seems to be due to a eombination of organic and emotional factors. Severe or even mild rickets is sometimes found to be the organic basis of this condition. Severe and prostrating illnesses occurring when the child is between 15 months and two years of age often eause a speech retardation and when the child begins to talk he talks indistinctly. This defect is often ascribed to tongue tie—to a too short frenum. rarely the ease.

We find especially in such eases a history of food finickyness in which the child refuses to a great extent green vegetables and lives on a diet composed very largely of carbohydrates and sweets,-low in vitamine content.

On the emotional side, such defects are often caused from the desire of the child to use a speech of his own and thus dominate his parents and nurses. It is often very hard to determine in such cases whether we are dealing primarily with an organic difficulty or an emotional difficulty. In most eases we have a combination of both.

Letter-sound-substitution is a defect which is characterized by the substitution of one sound for another, the most common type of substitution being "th" for "s". Sometimes the letter-sound-substitution is so extensive that the child's speech is unintelligible. The organic causes back of this defect are high palatal arch or malocclusion of the jaws. But it is very rare indeed to find such cases caused primarily by organic difficulties. These letter-sound-substitution cases are caused primarily by desire of the child to remain an infant or to dominate his parents and nurses.

The treatment for the oral inactivities and letter-sound-substitution is first, mental hygiene, teaching the child to give up his infantile methods of domination and to pass on to a more adult type of speech and conduct. Especially should the child not be given the things that he wants until he makes the effort to say the word clearly and distinctly. Where there is an organic element, the child should be given corrective phonetics. This work should be done with care. Too much insistance on phonetic drill may make the child speech conscious and give rise to stuttering.

Speech mirrors not only the normal development and organic integrity of the nervous system but is the clearest reporter of emotional development and emotional control.

Stuttering is a speech defect which is caused primarily by emotional factors. The child talks first to communicate his feelings and later on his thoughts. The child talks primarily to get attention; secondly he talks in order to express his emotion of love, also of anger and hate. He uses speech, therefore, as a means of adjusting himself to the social group, of asking for their love, and as a means of aggressive attack.

The speech mechanism is especially under the influence of the emotions. Even the subtlest emotions cause a change in the quality of the tone, in the rhythm of speech and in the breathing. To state the matter simply and rather superficially, we should say that stuttering is caused by timidity or anxiety on the part of the child in meeting certain situations. It is true that in certain cases of stuttering there may be a constitutional tendency on the part of the child to have poor speech. Also a tendency towards stuttering may be caused by the fact that the left-handed child is made to use his right hand. The primary factors in stuttering, however, are emotional.

From five to ten per cent of nursery children stutter for a period. Perhaps two or three per cent of them stutter for several months and about one per cent of the general population stutters.

We do not believe that any speech exercises should be used for the young stuttering child. The whole treatment should consist of a modification of the child's environment. Take off pressure, demand less speech response of the child, give him more freedom and remove the sources of anxiety from the child. In the schoolchild from six to twelve years of age relaxation exercises can be used and plays and pageants in which the child is stimulated to speak. We do not believe in the use of vocal exercises or phonetic exercises or breathing exercises in the treatment of stuttering. The treatment should consist primarily in teaching the child to adjust to situations with speech, through games, through plays, through pageants; and through the proper use of mental hygiene, building up in the child a feeling of confidence and security. In the adolescent and adult, a certain amount of psychiatric readjustment can be successfully used and in a very limited number of cases, especially those with marked anxiety states; and cases with mental symptoms approximating those of the obsessional neurotic, psychoanalysis may be used effectively. In this way, by modifying some of the personality tendencies as found in the stutterer, such as marked anxiety, sensitiveness or over-aggressiveness, the speech defect can be eliminated as the other mental processes approach normality.

GENERAL HYPERTHERMIA WITH HEAT LOCALIZATION BY RADIOTHERMY IN THE TREATMENT OF PELVIC INFLAMMATORY DISEASE

By WILLIAM BIERMAN, M.D., and EDWARD A. HOROWITZ, M.D., NEW YORK, N. Y. Read before the section on Obstetries and Gynecology, at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932. From the Gynecological Service and Physical Therapy Department of the Beth Israel Hospital, New York.

EAT has been applied in the treatment of the subacute and chronic stages of pelvic inflammation of the female, for the relief of pain and to hasten the absorption of exudates. For this purpose various procedures have been utilized such as hot sitz baths, hot vaginal douches, diathermy, and more recently the various vaginal hot water bags.

The development of a very high frequency oscillator which produces a general hyperthermia, combined with a new technique for concentrating electrical energy in the region of the pelvis, provided a new method for the application of relatively high temperatures in the treatment of pelvic inflammatory disease.

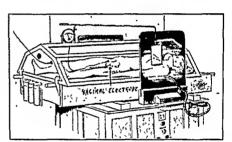

The technique for the systemic elevation of

temperatures in the human subject by means of the high frequency electric field in the radiotherm has been described by Carpenter and The method consists essentially in Page.1 placing the subject between the plates of a large condenser which forms part of an oscillating circuit. The oscillations in this circuit are produced by the use of radio tubes of appropriate construction (500 watt screen grid in push pull) with the necessary associated equipment for the attainment of a high frequency electric field of high intensity. The frequency commonly used for this work is approximately 10 million cycles per second, corresponding to a wave length of 30 meters. The condenser plates between which the subject is placed are large enough (50 x 80 cm.) to produce a field over a reasonable part of the volume of the subject, and are separated from one another by a distance of approximately one meter. The subject rests upon a stretcher between these plates but not in contact with them, and is kept covered during the treatment so as to prevent excessive loss of heat. With a total DC place current, of 0.5 amperes using two UV861 tubes, it is possible to produce an elevation of body temperature of about 70° F. in the course of an hour and one-half.

In order to produce a simultaneous increase of body temperature with a still higher increase in the temperature of the vagina the following method is employed,2 With the subject in place between the condenser plates of the radiotherm, an electrode is placed in the vagina. This electrode is connected, through an ammeter, to a small auxiliary metal plate suspended near one of the large condenser plates of the radiotherm. Under these conditions the electrical field produced in the region between the electrode and the condenser plate opposite to the one near which the auxiliary plate is suspended, is considerably higher than it is at any other part of the body. When the region to be heated is bilateral the pick-up plate is placed first on one side, and then moved to the other. With a pick-up plate of about 300 sq. cm. area, the distance between the pick-up and the condenser plate varies from 10 to 30 cm. The readings on the radiofrequency ammeter usually vary from about one to two amperes. With this technique it has been possible to develop temperatures ranging between 110° to 116° F. as indicated by a mercury thermometer inserted in the vaginal electrode while the temperature in the mouth is registered between 101° and 104° F.

It is possible to maintain a systemic elevation of temperature after it has once been established, by utilizing some device which retards heat loss, such as several layers of blankets, the application of hot water bottles, or a heated hood placed over the patient while lying in bed. Local elevations of temperature in the vagina may be maintained by introducing some other heat creating procedure such as diathermy.

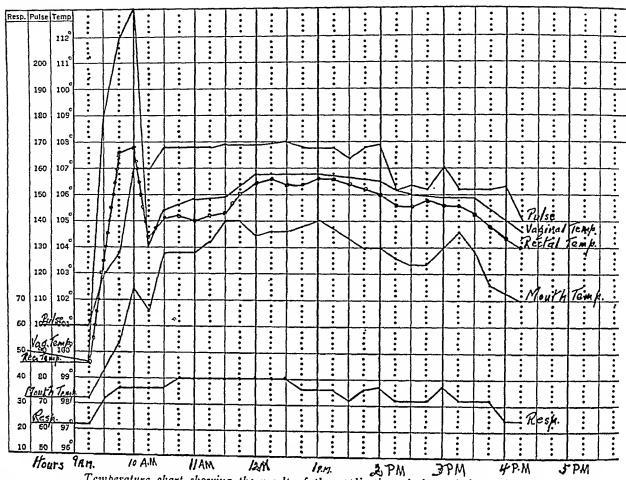

In preparation for the treatment the patient is given an enema in the early morning. Breakfast is limited to fluids. After the patient is placed in the radiotherm she is reassured by a description of the sensations which she will experience. She is carefully covered with towels to absorb the perspiration. The month and rectal temperatures, pulse and respiration rates are observed and recorded every ten or fifteen minutes. About 15 minutes after the current is turned on the patient begins to perspire and states that she feels warm. With the continuation of perspiration the towels may become moist and must then be changed or else there may be an unpleasant sensation due to the arcing of the current. Individuals react differently to the treatment. When the systemic temperatures are elevated to a high level such as 106° to 107° F the patient may develop various complaints such as headache, nausea, shortness of breath, palpitation, thirst, or a

This is a drawing showing the technique of applying general radiothermy with the special localization in the vagina.

sensation of numbness of the hands and feet. The advantage of the special localizing technique which we employ in the treatment of pelvic inflammatory disease is that it is possible to create marked temperature elevations in the region of the vagina with a comparatively mild degree of temperature elevation in the rest of the body. The uncomfortable sensations which the patient experiences are therefore much less than they would be were it necessary to elevate the temperature of the entire body to a higher degree.

Our first radiothermy treatment of a case from the gynecological service at the Beth Israel Hospital was administered on March 23, 1931. The patient had been operated upon by Dr. I. C. Rubin, for a large pelvic abscess

Temperature chart showing the result of the application of the technique of general radiothermy during a short period of time.

Blood Findings Before and After Temperature Elevation

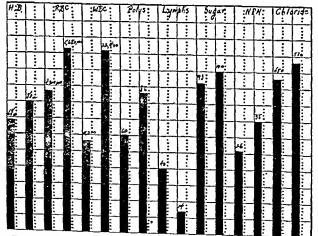

Chart showing the result of the technique of applying general radiothermy with a sustained elevation of systemic temperature over a period of several hours.

due to the streptococcus. Drainage was established by an extra-peritoneal abdominal incision. Thirteen days post-operative there was still a resistance on the left side. Three radiothermy treatments were then given, at intervals of two days, producing a general hyper-

pyrexia with higher elevation of temperation the vagina. On March 30th, a week aft the first treatment, Dr. Rubin found the maentirely gone. The treatment had apparent hastened resolution.

Our first radiothermy treatment of a gond rheal arthritis case was most dramatic. T patient, a married woman of forty-four, had subacute gonorrheal arthritis of two mont duration. The left hand and right foot we especially involved, with marked peri-articul reaction. There was a profuse cervical dicharge containing gonococci, but the pelvorgans were otherwise normal. After fiveeks in the hospital with slight improvemer Dr. A. A. Epstein decided to give this patie artificial fever treatment, using the radiother

Following one treatment with the radi therm, the joint pains completely ceased, the inflammatory reaction subsided, the vagin discharge diminished and the cervical smes became negative for gonococci. The block sedimentation rate, which had been 43 per cerbefore treatment, had dropped to 14 per certhree days later. Two weeks afterward, a fer gonococci were again found in the cervic secretion, but after a short period of lock.

treatment with silver nitrate, they again disappeared A score of examinations during the last year have shown no gonococei, and the joints have remained relatively normal

In addition to the two cases just reported, we have applied radiothermy to thirteen prients with pelvic inflammatory disease. The localizing technique, with the vaginal electrode, was used in every one of these cases. The patients were all hospitalized, and kept in hed during the period of treatment. Treatments were usually given every second day until a total of 4 to 6 treatments had been given. They were stopped during menstruation.

The red blood cell sedimentation rate was of value in guiding us as to the activity of the influimination, and in checking the results of treatment. Some of our blood sedimentation tests are reported in minutes, the rest in percent. The tests reported in minutes were done by one of us, using the Linzennieier technique with which acute influminatory cases give values under 1 hour—the more acute, the shorter the time. The percent results were from the hospital laboratory which uses the Fahreaus-Weisst technique with which influininatory cases give values over 8 percent—the more acute, the higher the percent

We will briefly describe these cases in chro

nological order

CASE No 3 G 11

Admitted May 12, 1931 Patient had been in bed for five weeks with abdominal pain fever and a profuse vaginal discharge. On admission, her temperature was normal Examina tion revealed a purulent urethritis and cervicitis, both positive for gonococei The uterus was anterior, not enlarged A left adnexal mass, fixed and tender, extended toward the cul de sae The right adnexa were tender, no mass was felt The leucocyte count was 16 200 with 82 per cent polys Sedimentation 32 per cent She was given three radiothermy treatments during one week. After the last treatment abdominal pain had almost entirely disappeared, and there was no longer any discharge Cervical smear was negative for gono cocci The left adnexa were smaller, but the right could be felt a little enlarged. After the second succeeding menstrual period gonocoeci were again recovered from the cervix but dis appeared after local treatment. The adnexal masses subsided Symptomatically, she has remained well

CASE No 4 H G

Admitted September 23 1931 Patient had an abortion performed August 10th A fetus and placental tissue came away, but lower

abdominal pain and fever kept her in bed for the six weeks preceding admission. On examination, the interus was anterior, not enlarged, fixed. The both adnexa were enlarged, tender fixed. She was treated four times. On discharge, there was no pain except for an occasional eramp at night, and no discharge Temperature was normal. Bilateral adnexal masses could be felt, slightly tender a little smaller than before. The sedimentation time which had been 56 minutes before treatment was now 90 minutes. This patient has felt well since leaving the hospital.

CAST No 5 L M

Admitted October 13, 1931, with chronic salpingitis and cervicitis. Blood counts and sedimentation rate were normal. Cervical smears were negative for G.C. Patient received four radiothermy treatments starting October 15th following which the vaginal discharge was very much less and the induration on the left side of the pelvis was less marked. She was seen in March, 1932, and found to be well.

Cisr No 6 M V

Admitted October 15, 1931, in her second attack of acute salpingitis Examination re vealed an inflammatory mass behind the uterus, extremely tender reaching to the height of the internal of Cervical smears were negative leucocytes 11 850 with 78 per cent polys. Within three days her temperature be eame normal and five days later, radiothermy treatment was started At this time the patient had constant severe pain in the left lower obdomen Sedimentation time was 19 minutes Twe treatments were given during a period of two weeks, at the end of which time the patient felt well, except for occasional pain in the left lower abdomen Discharge was scant Sedi mentation time 95 minutes Pelvie examina tion showed that the uterus was more mov able and there was only a slight thickening in the cul de sae Six days later the patient had no pain at all and the sedimentation time was 140 minutes

A few months after leaving the hospital she had a recurrence of abdominal pain for which she stayed in bed at home for several weeks. When seen in follow up on April 5th 1932 she still complained of pain. On pelvic examination. Dr. Rubin found the cul de-sac occupied by an irregular semi-cystic mass more marked toward the left side, evidently chronic diseased adnexa.

CASE No 7 B G

Admitted October 2nd 1931, with acute sal pingitis and pelvic peritonitis. She was treated

conservatively for twenty days. After the eighteenth day temperature remained normal, smears were negative for G. C. At this time there was considerable pain in the lower abdomen, more on the left side, but no muscle spasm was present. Sedimentation time was 25 minutes. She was given five radiothermy treatments. After the treatments she felt perfectly well. Examination by Dr. Lorber revealed a somewhat movable uterus and hardly any induration on either side. Sedimentation time, however, was still 33 minutes.

This patient has remained well. She was seen in April, 1932. There was no discharge and no induration.

CASE No. 8, H. B.

Admitted November 23rd, 1931. Patient had an attack of acute gonorrheal salpingitis six weeks before admission. She now complained of persistent abdominal pain, most in the left lower abdomen, and a profuse vaginal discharge. Her temperature was normal, sedimentation 30 minutes. Pelvic examination revealed an induration of the left adnexal area. She was treated six times. After the treatments the lower abdominal pains had disappeared and discharge was no longer noticed. Pelvic examination revealed only a slight resistance on the left side but no tenderness. Sedimentation time was 70 minutes. follow-up.

Case No. 9. G. B.

Admitted November 27th, 1931, with a post abortive pelvic infection of six weeks duration. Temperature was 101 degrees. Pelvic examination by Dr. Rubin on November 30th revealed that the right half of the pelvis was "frozen." The left parametrium was indurated but to a less extent than the right. The uterus was not made out separately or distinctly. Sedimentation was 30%. After five days rest in bed, temperature became normal, and after a day and a half of normal temperature, radiothermy treatments were started, on December 3rd. Six treatments were given. After the last treatment the patient felt and The uterus was movable with looked well. little pain. On either side was a somewhat tender mass. Sedimentation time was 5%. Three weeks later, follow-up examination revealed almost normal pelvic findings. Patient has continued to be well, and pelvic findings May 3, 1932, were normal.

Case No. 10. R. B.

Admitted December 16, 1931, patient had had her right ovary removed the year before. A month later she had a "vaginal abscess" which was incised. For the past year men-

strual periods lasted 12 to 14 days. Patient was admitted with a two days history of right lower abdominal pain with nausea and vomiting. There was evidence of salpingitis with pelvic peritonitis. The leucocyte count was 12,800 with 82% polys. Sedimentation 35%. Cervical and urethral smears were negative for G.C. Patient was treated six times with the radiotherm. On discharge, January 3rd, she felt perfectly well. There was still some induration on the left side. Sedimentation 15%.

Patient was seen April 5, 1932. She then complained of pain in the lower abdomen, not nearly so severe as when she was in the hospital. The pain was worse, especially on the left side, during menstruation, at which time she was obliged to go to bed. Examination revealed some enlargement of the left adnexa.

Case No. 11. B. B.

Admitted January 3, 1932. She had been in bed for eight weeks with lower abdominal pain and backache. Both adnexa were considerably enlarged, prolapsed and indurated. Temperature was normal. Leucocyte count was 11.400 with 77% polys, sedimentation time 20 minutes. Diagnosis, subacute gonorrheal salpingitis. Because of the persistence of the adnexal inflammatory masses, with a rapid sedimentation time, in spite of two months bed rest, it was believed by her attending gynecologist that surgery would probably be necessary. However, it was decided to administer radiothermy treatments in the hope of promoting resolution. She was treated five times with the radiotherm, starting January 4th, 1932. Treatment was stopped because she started to menstruate. On her discharge from the hospital the left adnexa felt smaller, but the right were more than 50% larger and felt semi-cystic. Sedimentation time was 16 minutes. Although the patient felt fairly well, and the temperature remained normal, there was unquestionably a tubo-ovarian abscess developing on the right side. She was re-admitted January 24th, 1932, camplaining of pain on the right side. Pelvic findings were unchanged, sedimentation time 25 minutes. Three more radiothermy treatments were given, during which she complained of vaginal pain and felt nauseated. There was no improvement in the pelvic findings. A week later the right adnexa were definitely larger. Sedimentation time was 56 minutes. At operation February 8th, there was a right tuboovarian abscess the size of a large orange and on the left side a retort-shaped pyosalpinx. There were no adhesions. Both adnexa were removed and drainage instituted. Pathological diagnosis; chronic salpingitis and ovarian abscess. Patient made an uneventful recovery.

CASI No 12 BIATRICT B

Patient had a large tubo-ovarian abscess with daily temperature of 103° Two radio thermy treatments were given which relieved her pain, but the mass was no smaller and the temperature no lower. No further treatments were given. Three weeks later the abscess was drained vaginally and the patient rapidly recovered.

In addition we treated two cases of chronic silpingitis with adherent retroversion of the uteus, (E. II and M. S.) who complained of bickache and vaginal discharge. Temperature leucocyte count and sedimentation rate were normal. The first of these patients received six treatments in December, 1931, and was relieved of her symptoms. Four months later she was still feeling well. The second case had three treatments in March, 1932 which relieved her backache for only a week or two like only change found on examination after treatment of these cases was the disappear ance of pelvic tenderness.

One case (AG) of subsiding salpingo ophortis was treated once, in January, 1932 and was "too nervous to treat further. We do not know how much the radiotheria contributed to her improvement.

CHAICM RESULTS

Five cases of subroute sapingitis and two postabortive pelvic infections improved rapid iv (Cases 3, 4, 6, 7, 8, 9, 10)

Three cases of chronic salpingitis improved (Cases 5, 13 and 14)

A gonorrheal arthritis case was cured after one treatment (Case 2)

In one subacute salpingitis case a tubo

ovarian abscess requiring operation, developed after radiothermy treatment (Case 11).

One large tubo-ovarian abscess was not

much affected by two treatments (Case 12)
One drained abscess resolved rapidly (Case 1)

RISUMT

It is difficult to evaluate the effect of treat ment in pelvic inflammatory disease, because one cannot estimate how long it will take an inflammatory process to subside. These inflammations usually do subside with rest in bed alone. However, it appeared in most of the cases in our series that the period of rest in bed and convalescence was shortened by the radiothermy treatment. In the subacute sal pingitis eases the clinical improvement was in most cases paralleled by a slowing in the rate of blood sedimentation.

The promptness with which the subjective symptom of pain was relieved is alone a good leason for giving this measure a further trial

From the small series that we have had to observe on our service, it would be unfair to draw broad conclusions. After further thor ough trial, we shall be able to select the type of cases, and the technique, which will give the best results with the radiotherm.

We are grateful to Dr I C Rubin, Director of the Gynecological Service at the Beth Israel Hospital of New York for help and advice, and to Doctors Lorber and Rashbaum of the Gynecological Service for permission to study their cases. We also wish to thank Dr W R Whitney, Director of Research Laboratories of the General Electric Company for placing the radiotherm apparatus at our disposal

Annual Meeting, April 3-5, in the Waldorf-Astoria, New York City.

INSPIRATION OF THE ANNUAL MEETING

The annual meeting of the Medical Society of the State of New York to be held April 3-5, 1933, promises to be of unusual interest and value to every member. The official listing would assign values to the features of the meeting in the following order:-1. Business: 2. Scientific; and 3. Social. But the individual member will unconsciously assign the first

place to the informal social contacts which he makes. He will go home happy and satisfied if he has met his old friends and made a number of new ones.

The meeting rooms in the Waldorf-Astoria, with their abundance of space, and their grouping on one floor, are themselves invitations to sociability. A member has only to

sit on a comfortable lounge and his friends are sure to appear as they stroll among the No one need exhibits and assembly places be lonesome at the meeting Friendly talks with individuals constitute a most valuable forum on the subject of County Society Administration, and an inspiration to practice the ideals set forth in the formal papers that are listed on the program. Come and compare rates with your fellow doctors

ENLARGEMENTS OF THE LIVER AND SPLEEN

This issue of the Journal contains the report of a case which will add to the slowly aceumulating knowledge of an obscure enlargement of the spleen and liver in babies Doctors frequently find the liver of a sick baby surprisingly large during any fever of toxic origin, and upon subsequent examinations find the liver has receded markedly. The liver of a baby is not unlike a clinical thermometer in its expanding with fever and returing to nearly normal as the symptoms are relieved

But there is the mysterious case of an in fant under two years of age who dies from manition after slow emaciation, whose spleen and liver are readily recognized as enlarged, whose lymph glands are generally palpable, and that is about all Our knowledge of this disease grows only through the autopsy findings, and it is important that they be recorded in the hterature

The article which is published on page 203 is a distinct contribution to the existing records of lipoid histocytosis, or lipoid spleno hepatomegaly, or Niemann-Pick's discase, as one may choose to call it While the condition is supposed to ocenr almost entirely in infants of Jewish parentage, this case occurs in pure Italian stock. The necropsy findings in the brain support the observation of other investigators that the ganglion cells of the central nervous system are markedly swollen and vacuolated, presenting an appearance similar to that described in the condition known as amaurotic family idiocy

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Medical Libraries -This Journal of February, 1908 contains the report of a Special Committee on Medical Librarics, which says

"A brief reference to the principal medical libraries and departments in the State of New

York may be in order

"The Library of the New York Academy of Medicine stands at the head. More has been done by that institution to encourage and advance medical libraries in this country than perhaps by all other agencies combined

'Albany is represented by the excellent medical department of the State Library, and this will benefit by the newer quarters now under way The original nucleus of this collection was gathered by the profession of Albany It is the only library of this class dependent on State support
"In Syracuse (Onondaga County) the work is

done through the medical department of the Um versity Library

"At Rochester (Monroe County) the collection of the Academy of Medicine constitutes a department of the Reynolds Library, the latter contribnting one half of its support as well as earing for it Originally the Monroe County Medical Society participated in this work, but is now en tirely divorced from it

"In Tompkins County, Cornell University has

n small medical library at Ithaca
"At Utica (Oneida County), a medical library

has recently been instituted

"In Brooklyn is the Library of the Medical Society of the County of Kings This is the only one of the series barring the collection of the Erie County Medical Society, that is directly affiliated with the State Society, and is the only one which also possesses a home of its own"

MEDICAL PROGRESS

Muscle Strain and Muscle Weakness .-- W. E. Tucker, writing in the Practitioner, December, 1932, cxxix, 774, calls attention to the fact that disabilities caused by a strain to a muscle or the symptoms shown by a muscle too weak to carry out its work are not fully realized. This is well illustrated by a flattening arch, caused by extra strain thrown on the muscles. The pain in these cases is not due to the flattening of the arch, but to the strain placed on the muscles and ligaments. Another instance is postural scoliosis in young children on whom extra strain, such as hard work at school or excessive standing, has been thrown. Medically an overtaxed heart muscle will show itself by cardiac dilatation or failure of compensation. Chronic muscle strain or muscle weakness undoubtedly plays a most important part in some cases of the following conditions: Tennis elbow, rider's nruscle, pain in the inguinal region due to strain of the abdominal obliques, pain along the sciatic nerve due to strain of the hamstrings, knee-strain from wasting of the quadriceps and muscles around the knee-joint following an injury or operation, a slack or weak muscle causing bursitis, sacro-iliac or lumbo-sacral strain and certain cases of occupational palsy. These conditions may be treated on the same principles: (1) Manipulation in those cases in which there is definite limitation of movement and pain produced by adhesons; (2) support to the part while the muscles are becoming strong enough to carry out their work—this is gradually diminished; (3) strengthening of the muscles by surging faradism and remedial exercises. Emphasis is placed on support to the part. Many patients with bursitis had diathermy, ionization and radiant heat for long periods without any results, but as soon as the muscle was supported and surging faradism and exercises ordered, they improved immediately.

A Clinical Type of Paroxysmal Tachycardia of Ventricular Origin in Which Paroxisms Are Induced by Exertion.—Frank N. Wilson, Shelby W. Wishart, A. Garrard Macleod and Paul S. Barker call attention to a type of ventricular tachycardia of ventricular origin in which moderate exertion almost invariably brings on an attack. They report four cases of this kind and review the cases described in the literature. While long attacks lasting several hours or days sometimes occur, a rapid succession of short paroxysms is more usual. In the pauses between these short attacks ventricular extrasystoles occur singly or in salvos of two to five or more. Rest is often followed

by a gradual decrease in the length and frequency of the paroxysms and a return to normal rhythm. This condition is quite different from paroxysmal tachycardia of the ordinary type and may be easily overlooked. There is often no sign of structural heart disease and no disturbance of the cardiac mech-It is only when the anism while at rest. patient is examined after exertion that the real nature of the disorder is discovered. As a rule the disability is greater than that produced by a well compensated valve lesion or by continuous auricular fibrillation without congestive failure. There is little tendency to recover. There is slight evidence to indicate that coronary disease may be the cause of this disorder. Typical anginal pain did not occur in any of the cases reviewed. In the case histories general arteriosclerosis, arterial hypertension, diabetes and luctic infection, which are relatively common in coronary disease, were conspicuously absent. The relation of the attacks to exertion and excitement, the absence of signs of structural heart disease, and the fact that the paroxysms are precipiated in some cases by adrenaline and atropine suggests that the cause of the disorder may lie in the vegetative nervous system rather than in the heart. In one of the authors' cases a long paroxysm of ventricular techycardia was frequently interrupted by short attacks of auricular tachycardia. Quinidine may be regarded as a specific remedy in this type of tachycardia in the same sense as digitalis is so regarded in auricular fibrillation. In some cases small doses of quinidine completely prevent the attacks and enable the patient to return to his customary mode of life.—American Heart Journal, December, 1932, viii, 2.

Observations on the Heart in Old Age. Frederick A. Willius and Harry L. Smith refer to a previous publication in which Willius presented a clinical study of the hearts of 700 aged persons, showing that most aged persons, even in the presence of heart disease, possess hearts of unusual quality. Statistics clearly prove that the greatest mortality from heart disease occurs between the fiftieth and seventieth years of life, and that persons who have survived this period are more likely ultimately to succumb to other diseases, such as carcinoma, pneumonia or nephritis. The present study comprising 381 patients, ranging in age from seventy to ninety-nine years who came to autopsy, confirms the statements made above. Of the 381 patients, 59.4 per cent. were between the ages of seventy and seventy-four years, whereas 15.7 per cent. were eighty years or older. The ratio by sexes was five men to one woman. Varying degrees of coronary sclerosis occurred in all cases but the involvement was moderate to advanced in 72.5 per cent. of them. Likewise, aortic sclerosis was a constant finding, but existed in from moderate to marked degree in 80 per cent. of the cases. Sclerosis of the valves occurred in 92.7 per cent. of the cases. Cardiac disease other than arteriosclerosis, was present in 16.4 per cent. of the cases. The blood pressure readings in 371 cases indicated a tendency to hypertension. The causes of death in this group of patients were diverse, carcinoma leading the list with 93 cases, and pneumonia ranking next with 69 cases. In only 48 cases or 12.6 per cent, of the group was death attributed to Among these, hypertensive heart disease. heart disease was present in 14 cases, cardiac failure consequent to healed cardiac infarction in 11 cases, acute cardiac infarction in 11 cases. coronary sclerosis with angina pectoris in 7, aortic stenosis in 3, and syphilitic aortitis and chrouic adherent pericarditis, each in 1 case. This study and the former paper by Smith do not indicate that there is increase in the weight of the heart in old age, except such as occurs in the presence of disease. Low blood pressures were found infrequently in this group .-American Heart Jaurnal, December, 1932, viii, 2.

Radiographic Résumé of Rickets and Scurvy. -I. Spencer Silverstein, writing in the Archives af Pediatrics, December, 1932, xlix, 12, describes the roentgenographic findings in rickets and scurvy. As these diseases are both nutritional disorders, they present themselves according to the sequence and amount of altered metabolic disturbance. Each may occur separately, or they may occur together. In rickets the more commonly involved bones are those of the skull and thorax and later the long bones. The cranial bones show areas of decreased density with prominence of the frontal and parietal bosses. The head is greater in circumference than that of a healthy child of the same age. The suture lines are widened, and the fontanels are late in closing. All of these findings are seen on the x-ray films. The chest signs are manifested by enlargement of the costochondral junctions, known as beading of the ribs. When this is present on both sides of the sternum, there is produced what is known as the rachitie rosary. The long bones undergo changes of atrophy, absorption, bowing, and occasionally fractures. The epiphyses become saucer-shaped and hollowed out, with a margin of fuzziness and indistinctness. There are very slight periosteal changes. The rountgenographic aspect of seurvy presents a ground glass, ghost-like appearance in the center of the cancellous portion of the long bone. The epiphyseal end is saucer-shaped and hollowed out, but is sharp and chalky in appearance. The earliest evidence of its presence is a white line in the shaft margin of the epiphyseal zone, this line being thinner, denser, and sharper in out-line than in rickets. The scorbutic process frequently has a tendency to spread out into the soft tissues beyond the line of the shaft. If the condition is allowed to continue, a porous zone is formed behind the chalky line, and if the process advances, there may be a fracture at this point, with later a stripping and elevation of the periosteum and hemorrhage under this elevation. Soon fibrous changes take place under the periosteum and then formation of calcareous deposits is seen, irregular in outline and arrangement, and of greater density than bone.

Influenza,-After reviewing the etiology and pathology of influenza, H. Morley Fletcher describes four clinical types of the disease; (1) Simple catarrhal; (2) pneumonie; (3) gastro-intestinal; (4) apyrexial. The last named type is not common and may be difficult to recognize unless it occurs during an epidemic. The general symptoms are those of an ordinary attack of influenza, but there is no fever. The complications and sequels of influenza are numerous and at times serious. From the first onset it should be clearly recognized that the potentialities for ill in influenza are great. During an epidemic it is almost impossible to avoid infection. Delicate persons should avoid public gatherings. Bed-rooms and sittingrooms should be well ventilated, Gargling the throat and washing out the nasal passages have considerable prophylactic value. A 1:4000 solution of potassium permanganate in nor-nial saline is useful for this purpose. Vaccines do not seem to be so effective in preventing an attack as in preventing complications or lessening their severity. Every effort should be made to increase the resistance of the patient by good food, with an adequate supply of vitamins A and D, and plenty of sleep. With the onset of an attack of influenza the patient must be given absolute rest in bed in well-ventilated room. The temperature should be maintained at a constant level of about 62° F. day and night. The bowels should be cleared with calomel followed by a saline. The diet should be mainly milk, with a proprietary food such as ovaltine, bemax, or Benger's food. Water or lemonade may be given freely, with the addition of glucose. In

the early stage of an attack the following mixture generally relieves the pain in the limbs: Quinine sulphate, 1 grain; sodium salicylate. 10 grains; syrup of orange, 30 minims, and chloroform water to make I ounce. This mixture is taken every four hours, and 20 to 30 grains of potassium citrate may be added. The frequent use of a gargle or mouth-wash is indicated. The following prescription is recommended: Potassium chlorate, 8 grains; boracic acid, 5 grains; tincture of myrrh, 10 minims, and water to make I ounce. Phenacetin and acetylsalicylic acid will generally relieve the splitting headache. Hypnotics may be given for the insomnia. For the painful cough inhalations often give relief; a teaspoonful of the following mixture is added to a pint of water at 150° F. and the vapor inhaled: Tincture of benzoin, 60 minims; menthol. 3 grains, and oil of eucalyptus, 3 minims. an expectorant the following prescription gives satisfactory results: Sodium bicarbonate, 15 grains; potassium iodide, 2 to 4 grains; wine of ipecac or tincture of squills, 71/2 minims; syrup of tolu, 30 minims; spirits of chloroform 10 minims, and infusion of senega to make one ounce. For congestion at the bases of the lungs a linseed poultice usually gives relief. A failing heart should receive prompt attention. Great care should be taken during convalescence. — Practitioner, January. 1933, cxxx, 775.

The Treatment of Local Frostbites.—Frostbites, according to Rudolf Campbell, who writes in the Schweizerische medizinische Wochenschrift of December 17, 1932, may be classified as of 3 degrees, according to their gravity: (1) Congelatio erythematosa, (2) congelatio bullosa, and (3) congelatio escharotica. In every third degree frosting, the other 2 degrees are also present, and not until 2 or 3 days have passed is it possible to evaluate a case correctly on the basis of its reaction to treatment. Campbell's experience in high mountain regions has led him to use the following procedure: The patient is brought into a warm room and his trunk wrapped immediately in warm covers with application of all available kinds of external and internal heat, with a view to promoting the best possible circulation for the sake of the frozen peripheral parts. Meantime the frozen members are placed in a cold water bath at 8-16° C., in order that the thawing out may be accomplished gradually, the temperature of the water being regulated by the addition of snow and ice as needed. The patient is urged to perform all the active movements he can with the frozen member. The physician strokes the frozen parts toward the heart with a wet

towel, with care to remove from time to time any ice that may form on the skin. Through freezing of the water upon the surface of the skin the cold necessary for this physical process is withdrawn from the frozen member, and the latter is thawed out quickly, safely, and, as it were, without secondary effects. If the frostbite is on the face, the same result is effected by passing cold compresses over it. Rubbing with soft, dry snow is always useful, but the use of hard frozen snow is to be condemned, since it may inflict wounds that will admit infection with the possibility of fatal results at a later time, inasmuch as a frozen part is singularly defenseless. The operator's own hand must be perfectly clean and should be wrapt in a woolen cloth or glove to prevent its freezing while at work. Immediately after the part is thawed out, antiseptic treatment should be used. The member is placed in elevation, in a freely movable position, in semiflexion, with strict avoidance of any pressure. The patient is again urged to undertake active movements systematically, while supportive and stimulating measures are carried out for the general condition. Where the patient is unconscious, no time should be lost before giving stimulation by enema or infusion. Light massage toward the heart is then given every 2 to 3 hours, with mild skin stimulants such as camphor or camphorated oil. Hot air treatment and the quartz vapor lamp are useful in this stage, with Bier's hyperemia reserved for use first after arterial hyperemia has been established. Later stages in severe cases demand care of the blisters and transudates and of secondary infection which always finds a good culture medium in the lat-Campbell recommends Tschmarke's method of radical removal of the blisters with all epidermal shreds, soaking up of the transudates, and removal of the jellylike masses of serum and fibrin with aseptic precautions, after which the deep necrotic parts without blisters are treated with iodoform, dermatol, or the like, while an ointment of tannin in lanolin is applied to the aseptic parts.

Cellulitis of the Breast and Angina Pectoris.—A case reported by Paul Veil in the Archives des Maladies du Cœur of November, 1932, is highly instructive in that it holds new elements responsible for the production of certain apparently typical attacks of angina pectoris. A woman of 42 had for 2 years been subject to extremely painful cardiac seizures, resulting at length in constant retrosternal pains radiating toward the neck and even the inferior maxilla. The left arm was in a state of perpetual swelling, with its little finger painful, and extrasystoles with syncopations

time afterward pressure on the gallbladder had caused a lancmating pain, and at the mo ment of its syncopations the heart had slowed This made it seem reasonable to think of irradiation of hepatic origin, and of nervous Such a view was supported by bradye irdin the circumstance that introglycerin had no effect and that even a milk diet was ill tolerated On the other hand the angual attacks were of the most typical kind, and the presence of a diphasic T wave in the electrocardio gram seemed decisive for this diagnosis. Light was thrown on the subject when massage of the left arm rapidly reduced its swelling, for the patient now called attention to the fact that her left breast had for some time been larger than the right Upon examination it was found to be filled with a mass that gave the impression of a saturated sponge and was Obviously, in a very painful on pressure state of cellulitis, it yielded to massage in a few sittings. As its regression continued the pains grew less and disappeared, together with the diphasic T wave, the patient was transformed, and her cure has persisted thus refutes the classic view that the presence of a diphasic T wave invariably means an orgame coronary process, and that a diagnosis of true anging pectoris can be made on the sole basis of such an alteration. For here the diphasis was certainly due to nervous influences the point of departure of which was probably at the level of the nerve branches caught within the cellulitie masses of the breast and from which arose the pain localized by a paradoxical play of the neurocardine pianoforte in the same zone as that of true angina Pyretotherapy in Experimental Syphilis, and Its Association with Chemotherapy -Accord ing to Ch Richet fils and J Dublineau, the treponema is extremely sensitive to heat a series of experiments covering 18 months these authors inoculated rabbits with trepone mas that had been subjected to a temperature

increased the agonizing pain, which no medi-

cine could relieve. It so happened that an

attack of paratyphoid 10 years before had been

followed by attacks of migraine, for a certain

Pyretotherapy in Experimental Syphilis, and Its Association with Chemotherapy—According to Ch. Richet fils and J. Dublineau, the treponema is extremely sensitive to heat. In a series of experiments covering 18 months these authors included rabbits with treponemas that had been subjected to a temperature of 41° C in a water bath for 30 to 120 minutes. In a group of 11 animals which received intra-testicular moculations it appeared that the virulence of the micro organisms had been entirely lost no chance nor any primary orchitis developing and the Memicke test proving negative in the 6 animals upon which it was tried after a resistance of more than 24 days. The mobility of the treponemas was attenuated after 30 minutes at 41° C and was practically nil after 80 minutes. On the other hand, of 10 controls 7 developed a typical orchitis with

ultramicroscopic treponemas and positive Memicke In tests to determinate the effect of pyretotherapy upon syphilis already present in rabbits, the authors observed cures in 3 and no cures in 2, where the rabbits were kept in a water bath in such a way that the rectal temperature rose on an average to 415° or 425° C in the course of 15 or 20 minutes When arsenotherapy in infracurative doses (less than 9 ing novarsenobelizol per kilo rabbit) was associated with pyretotherapy, it appeared always to bring about a complete physiologic cure, (4 cases) Although not yet ready to publish in detail their work in human cases, the authors report that in 38 cases of primary or secondary syphilis submitted to this associated therapy, a clinical cure was observed, and in 36 of these a positive Wassermann became negative at the end of the first series of treatment -Bulletin de l'Academie de Medecine, December 27, 1933

Calcium as an Analgesic -The good effects of calcium for the relief of pain in chronic neuralgia neuritis rheumatism and incoercible headache are pointed out by Godfrey Tavares in the Munchener medizinische Wochenschrift of December 9, 1932 The author has been making use of calcium laetate for this purpose during the last 15 years. Apparently the gen eral acceptance by the medical world of cal cium as an analgesic has been hindered by the moderation of its analgesic properties action begins slowly, after a lapse of hours, and is little intense, but is, on the other hand durable and lasting Tavares has brought about complete cures in patients who had had recourse to the whole armamentarium of classie analgesics without obtaining relief. He had the best results from oral administration the soluble salts when thus given everting a more energetic action than under intravenous or intramuscular injection. Since solutions of calcium lactate are very short lived, the best method is to dissolve I 2 gm in a little hot water after each meal and give it to the patient in a glass of cold water. The disagree able taste of calcium lactate does not neces sarily call for correction but in the milder cases it may be covered up by a little lemon juice which facilitates its solution in cold water Sugar may be added or the lactate may be combined with the glyconate of calcium which is nearly tasteless Taveres has always, however had better results from calcium lactate than from other salts of calcium the stomach is sensitive it may also be advisable to use weak solutions as enemas (2 gm in 100 cc water) as the author does in cases of chronic diarrhea but for most cases the oral use is recommended and only after meals

LEGAL

ILLEGAL PRACTICE OF MEDICINE BY A LICENSED PHYSIOTHERAPIST

By LORENZ J. BROSNAN, ESQ. Counsel, Medical Society of the State of New York.

The strict enforcement of the provisions of the Education Law relating to the illegal practice of medicine is of great importance to the welfare of the people of this State. A recent case involving the illegal practice of physiotherapy, decided by our Court of Appeals, is of great interest to the medical profession. A consideration of the facts in the case and the ruling of the Court requires, in the first instance, an examination of the statutes involved.

The practice of medicine is defined in Article 48, Section 1250, subdivision 7 of the Education Law as follows:

"A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition."

The chapter of the law which contains the statute above quoted, also regulates the practice of osteopathy and physiotherapy. The law is definite in providing that an osteopath may not administer drugs or perform surgery with the use of instruments. The law is even more strict as to physiotherapists. They may not "administer drugs or practice medicine . . . except to treat diseases under the supervision of a duly licensed physician." Physiotherapy is defined in Section 1262, subdivision 2 of the Education Law as follows:

"Physio-therapy as used in this article is hereby defined as the use of actinotherapy, hydrotherapy, mecanotherapy, theremotherapy, and electrotherapy, exclusive of the x-ray."

In the case under consideration, criminal charges had been brought against a licensed physiotherapist charging him with illegally practicing medicine. Proof was introduced at the trial to show a violation of the provisions of the Education Law and a failure to comply with a rule of the regents which provides as follows:

"Registered physiotherapist shall keep a written prescription signed by a licensed physician for each patient given physiotherapeutic treatment. The prescription shall state the diagnosis and the type of treatment ordered. Such records shall be open to the inspection of the department of education at all times."

The physiotherapist was convicted and an ap-

peal was taken to the highest Court of the State. In affirming the conviction the Court in its opinion described the practice of physiotherapy as permitted by law to be as follows:

"...it would seem that a patient having consulted a licensed physician of his own choice might after examination and diagnosis be found in need of physiotherapeutic treatment. His physician then writes for him a prescription stating the diagnosis and type of treatment ordered by him and he takes it to a licensed physiotherapist in the same manner as he might take a prescription for drugs to a pharmacist to be filled. The theory that the physiotherapist acts under his own supervising physician does not comport with the practice that the physician examines and prescribes before the physiotherapist sees him."

In the case before the Court the defendant claimed that when he was consulted by the patient whom he undertook to treat, he first went to the telephone unknown to the patient and consulted with a licensed physician with respect to the physical examination which he had just made of the patient. He claimed that he had discussed the findings of the examination with the doctor, and that the doctor had by telephone told him the precise sort of diathermy treatment to administer to the patient. The defendant claimed that after the treatment had been given, the doctor with whom he had had the telephone conversation had come into the defendant's office where he tried to examine the patient, but to this she protested. Apparently, with no further examination than that which had been made by the physiotherapist previously, the doctor proceeded to write out a prescription and a direction card as to her treatment. The defendant claimed that by reason of the said facts he had not rendered the complainant any treatment except "under the supervision of a duly licensed physician," and therefore he claimed that he had not violated the provisions of the law.

The Court, however, answered these contentions with logic and finality, stating:

"Adopting for the purpose of the decision so much of defendant's contention as is consistent with the evidence of the People's witness, who was a police woman attached to the crime prevention bureau and temporarily assigned to the attorney-general's office to get evidence against illegal practitioners of medicine, we think that a case of practice of medicine by defendant was made out; that defendant treated the witness for rheu-

matism, or at least for her complaint, on his own diagnosis and not under the supervision of a duly licensed physician and on his written prescription

"Defendant's office and office equipment and his conduct had all the indicia of a doctor's office and a doctor's treatment. When the People's witness cilled at defendant's office she met the defendant To her question if he was Dr. M. he replied that he was, he asked her what was the trouble and she told him she had been suffering with great pains in her hands, he took her family history and made an intimate personal examination of her, he tested her reflexes and looked into her throat, palpated her abdomen, took a specimen of her urine for examination and examined it and told her he found a trace of albumin took her blood pressure and was about to take a blood test but under her objection he desisted. He then had her place her hands under an electric lamp known as a thermolite

"After about half an hour of this treatment in came Dr A, who was a heensed physician wanted and tried unsuccessfully to examine the patient and he wrote a prescription. She refused his services She said, 'Who are you? I didn't send for you' She then pud defendant \$5 and got out of his office Asked by defendant's eounsel if she was not sore because Dr A had 'spoiled her game,' she said that her game was completed before he came. To account for the presence of Dr A we must take as true the evidence that he was summoned to defendant a office by or for the defendant. It might be assumed also that he in structed the defendant over the telephone what to do until he arrived, and it is not contended that such practice is unusual. The trouble is, however, that such practice has no sanction whatever in the law, which defines what a heensed physio therapist may do. To say that the statute contemplated that such a one may make a complete exammation of a patient, take his history, report the results to a heensed physician of his own selection over the telephone, act on his verbal instructions until the physician arrives, then have him go through the motions of handing the patient, who triples him, a prescription without any independent examination on his part, is to open the door so wide to exasion as to leave the statute a mere futility. All this procedure may be quite harmless but it is not permitted by the law.

"If on the People's evidence in this case the triers of fact could not find that defendant held lumself out as being able to diagnose and treat diseases, it is difficult to see wherein the statute affords any protection to those who may be attracted to the office of a physiotherapist by his advertisements in connection with rheumatism and like diseases, and into the hands of one who, without adequate medical training, essays to exanime them for human ills, say what treatment they need and administer it to them, without any prior supervision of a duly beensed physician and without a written prescription stating the type of treatment ordered. When such conduct is a fraud or a pretense, as it appears to have been in this case, the courts are not so blind and dumb as to be taken in by it It is no defense that the defendant acted in good faith or did what was eustomary The only question is whether he violated the statute Of this there seems to be no doubt "

The decision is unquestionably a right and just one. The attempted defense was a subterfuge and was given the shrift it deserved by the Court of Appeals.

BURN FOLLOWING USE OF CAUTERY KNIFE

In this case a doctor who specialized in surgery was consulted by a middle-aged woman complaining of an enlarged abdomen. The doctor examined her and diagnosed her condition to be a uterine tumor. He undertook to operate on her with respect to the condition, and in the operation made use of a radio cautery knife.

Before the doctor entered the operating room to proceed with the operation, one of the nurses prepared the patient for the use of the said apparatus, placing a wire mesh under the back of the patient just before the anesthetic was given to her The doctor then opened the patient's abdomen, separated the tumor from the walls of the uterus and closed the patient's abdomen. The operation was uneventful and the patient was returned to her room

After she came out of the ether, it was discovered that the patient had a burn on her back. The doctor examined her and found a third-degree burn about three inches in diameter, at

about the region where the mesh attached to the radio cautery machine had been applied to the patient's brek. The doctor dressed the burn regularly and it healed rapidly, and when the patient was ready to leave the hospital and recovered from her abdominal condition the burn was practically healed.

The patient instituted an action against the doctor charging that he had improperly placed an electric heating pad beneath her at the time of the operation and had thereby caused her to suffer a severe burn, which burn caused her to be disabled for a period of about four months. The action was brought on before a judge and jury, and at the close of all the testimony a motion was made on behalf of the defendant to dismiss the complaint on the ground that the plaintiff had not established a cause of action against the doctor. The said motion was granted by the judge, there by terminating the action in favor of the defendant doctor.

ALLEGED NEGLIGENCE IN PLASTIC SURGERY

A girl about seventeen years of age consulted a doctor whose practice includes a great deal of plastic surgery. She gave the doctor a history of having suffered from some severe burns on her face, which she had sustained about seven years before. His examination showed extensive burns on both sides of plaintiff's face including both lips, and a scarring and contraction of her upper left eyelid which prevented her from completely closing her left eye. She also suffered from a defect in breathing because of the deformity resulting from her severe burns.

The doctor told the patient that a series of operations might improve the conditions which he found, and at the request of the patient and her parents the doctor undertook to perform said operations. The treatment which he rendered to the patient extended over a period of about a year and a half and included nine separate operations which, briefly, may be summarized as fol-lows: First Operation: Scar tissue was excised from the right side of the face and skin was advanced to cover the defect. The left side of the face was repaired by rotation of skin from the neck. Second Operation: Skin was dissected from the neck, pulled up to cover raw areas and sutured in place. Third Operation: The tissues of the fact bilaterally were readjusted. Fourth Operation: The scar was excised from the left eyelid to relieve ectropion, and the defect was covered by tissue from the right upper eyelid. Fifth Operation: Hypertrophied scars of the face were treated by insertion of silk sutures under the scars to promote lymphatic drainage. Sixth Operation: Scar tisue was removed from the left side of the nose, and adhesions were excised between the left upper and lower eyelids. Seventh Operation: Face and neck were further repaired and a skin graft applied to the left upper lip. Eighth Operation: A further attempt was made to correct the condition of the left eyelids, transplanting certain skin. After each of said eight operations the patient progressed satisfactorily and the ninth operation was undertaken for the purpose of correcting the ectropion of the upper left eyelid. Said operation consisted of releasing of scars and inserting a Thiersch's graft on a mold, which mold was held in place by paraffin sutures. Before surgical intervention the eyelids were closed with sutures during this operation.

The patient's post-operative condition after the ninth operation was normal until the third day, when the plaintiff complained to the nurse in charge of her case of a severe pain in her left eye. One of the assistants of the surgeon in charge of the case was notified, and he removed

the dressing and sutures and found a discharge from the left eye. He called into consultation the hospital eye surgeon and the diagnosis was made of an infection of the cornea. Atropine and argyrol were administered to the eye. The surgeon who had performed the series of operations was called in and examined her, and he concurred in the manner of treating the condition and turned the case over to the attention of the director of the eye service at the hospital.

While the case was under the care of the said physician, a sloughing of the cornea developed and the ocular conjunctiva became swollen due to the infection. The vision at this time was considerably impaired. The upper and lower lids were edematous and congested, and the eyeball was covered with a serofibrinous secretion. The cornea was covered with a fibrous exudate which was adherent to the superficial area of the cornea.

The patient received very careful attention at the hospital with respect to the infection. From time to time sloughing areas were removed from the region as necessary, and about eight weeks after the ninth plastic operation the patient was discharged from the hospital. At the time of her discharge from the hospital the infection had disappeared and the eye condition had considerably improved.

Suit was brought against the surgeon in which it was claimed that the last operation performed by him and two of the earlier operations were negligently performed, so that as a result thereof plaintiff was caused to completely lose the sight of her left eye. The further charge was made in the complaint that in addition to being totally blind in the left eye, the plaintiff's right eye was affected and it was claimed that plaintiff would eventually lose the sight of said eye. In the plaintiff's bill of particulars the specific charge was made that during the last operation performed by the defendant, he negligently struck and injured the epithelium of the cornea. The case was brought on for trial before a Supreme Court Judge sitting without a jury, and at the close of the entire case the court held that the plaintiff had failed to show that the defendant in his treatment of the case had failed to follow proper practice and, therefore, directed a verdict in favor of the defendant. A notice of appeal was thereupon served on behalf of the plaintiff, but after several months had elapsed, the plaintiff having taken no steps to prosecute said appeal, an application was made to the Appellate Division to dismiss the appeal and said application was granted. thereby finally terminating the matter in favor of the defendant doctor.

NEWS NOTES

THE ANNUAL MEETING, APRIL 3-5, 1933

The plans for the Annual Meeting of the Medical Society of the State of New York, at the Waldorf-Astoria, New York City, on April third, fourth and fifth, are taking shape rapidly. What promises to be an unusual meeting is being arranged

On Mondry, April third, throughout the City, there will be operative and clinical demonstrations by the outstanding men of New York Dr. Peter Irving, who has this matter in hand, should be communicated with by those desiring to take

part in the Chinical Day

Fire Scientific Exhibit, in the limits of Dr Frederic E Sondern promises to be of an unnique exhibition. The fine cooperation of the men in New York is appreciated by the officers

The handling of the affairs of the State Society at the meeting of the House of Delegates needs no comment. This year weighty problems confront the profession, and reports, which will soon he published, will give an idea as to the scope and the multiplicity of the problems which will press upon the Delegates for solution

Dr Arthur J Bedell, of Albany, announces an unusual scientific program at both the general meetings and the section meetings. There will really be three general meetings. There will be one on Tuesday afternoon, April fourth at which scientific problems confronting both the medical and the dental profession will be threshed out. On Wednesday afternoon April fifth there will be a general meeting at which problems conjointly concerning surgical and medical aspects will be discussed. In addition to this there will be an

open forum meeting on Wednesday evening April fifth at wluch it is hoped the President of the American Medical Association will be present

The public will be told what they should know concerning such pressing problems as cancer diabetes, rheimatism gotter heart discase appendicutes and tuberculosis. These topics will be discussed by such authorities as Ewing, Joslin, Crile Herrick, William Haggard and Linisly R Williams. Of course this is a tentative program,

subject to change

There will be a Banquet held on Tuesday evening, April fourth, and no one who has the time free should fail to come. Outstanding national figures will talk on the pressing problems confronting our profession. Tickets will be sold in the order in which they are applied for Those asking for tickets will be seated in the sequence of their requests for them. It is expected that there will be many who will put off getting their tickets to the last minute, their names will not be listed as among the guests, nor will they get an assigned seat unless the request for the ticket is in the hands of the Committee before the Saturday preceding the meeting. Of course, tickets will be available at the meeting but those getting these last minute tickets must not feel aggrieved because they are seated at unlisted tables. Following the dinner there will be dancing for which no extra charge will be made

During the meeting, it is proposed to hold an educational program on preventive phases of medicine for the public. This will be broadcast

Samufi J Kopetzky, Chairman Committee on Arrangements

COMMITTEE ON PUBLIC RELATIONS

MEETING OF JANUARY 16, 1933

The Committee on Public Relations met on January 16 1933, at 1 30 PM at the Fort Schuyler Club in Utica There were present Drs Sadlier, Fisher, Hambrook, Mitchell, Cinningham, and Ross, also, Dr Lawrence, Dr J D Olii County, Dr Thomas H Gounty, and Dr S Lawrence and Lewis Counties There was no representative of Madison or Herkimer Counties

Industrial Health Talks—Dr Farrell reported for Oneida County regarding the Third Annual Series of Industrial Health Talks sponsored jointly by the Oneida County Medical Society, the

Utrca Dental Society, and the Industrial Relations Department of the Y M C A This health educational program ran from December 7th, 1931, through to March 10th, 1932 (Journal, Oct 1, 1932, page 1139)

Health information and guidance were brought to nearly three thousand men and women employees of the several industrial concerns where the talks were given Thirty-four noon-day health lectures were given by twenty physicians and dentists. This comprised the speaking personnel under the leadership of the Public Relations Committee

The Director of the Industrial Relations De-

partment of the Y.M.C.A. who comes into close and intimate contact with the employers and employees of these mills, declares the project has been eminently successful from the standpoint of results, although the total attendance at the thirty-four talks has sagged somewhat, due to the employment situation.

The lectures were presented by fifteen physicians and five dentists of the respective societies, each of whom devoted twenty-five minutes of volunteer service at each of the thirty-four sessions. Subjects covered in the Third Annual Series were "Heart Strain in Industry," "Visual Efficiency," "Coughs and Colds," "Wounds and Bruises," "Contagious Diseases," and "Care of the Teeth."

Dr. Farrell further said that this work entails a tremendous amount of detail which no busy doctor could do. It is essential, therefore, to hook up with some lay organization who will make contacts, and arrange dates.

Nurses' Organizations—Dr. Farrell reported regarding the organizing of nurses of the county into a group in which the physician would sit. Dr. Hambrook stated that in Rensselaer County and in Greene County they have the nurses organized under a county health committee. Dr. Cunningham stated that the same was true in Warren County. Dr. Sadlier stated that the same was in operation in Dutchess County. The purpose of this organization which includes all nurses outside of private nurses was to give nurses a medical viewpoint. Dr. Ross was asked regarding the organization in Suffolk and he said that there is excellent cooperation of the nurses with the physicians.

Dr. Fisher said that the close professional contact with the nursing associations in Oncida County was a valuable asset. The Social Agencies Association in Oncida County is made up of fifty health and welfare agencies.

Allied Professions—Dr. J. D. Olin, representing Jefferson County, reported regarding a series of talks before the Medical Society by representatives of the allied professions, such as dentists, pharmacists and nurses. The County Society had instituted health talks by physicians before other groups, including lay groups, such as the Grange, 4-H Clubs, and industrial groups. He said that it was hard to get physicians to do this in Jefferson County outside of the City of Watertown.

County Health Department—Dr. Olin stated that the Public Health Committee has a mandate from the County Society to advocate the organization of a county health department, but that a few members have balked the desire of the County Society. He stated that the Board of Supervisors was reluctant to support a health department this year.

County Nurses—The employment of county health nurses was abolished this year in Jefferson

County on the plea of economy. There is one public health nurse in Watertown and two in the county at large. Although the Public Health Committee of the County Society and other organizations protested, it had no effect. In some other counties of the state no appropriations have been made this year for county public health nurses. This is an unfortunate situation. It was suggested that the Journal publish an editorial on this subject.

The Family Doctor-Dr. Olin said: "The general practitioner must be recognized as the keystone in the arch of the foundation of medical The general practitioner is suffering from the high degree of specialization prevailing, and the people are often the emergency patients of a number of specialists, rather than the clients of general practitioners as they should be. There should be a readjustment of monetary awards for medical services so that a general practitioner might be raised from the position of an emergency man to that of director of the physical well-being of his client-a man who will make frequent appraisals of the condition of his client and obtain for him from time to time or in emergency such special advice and treatment as his case requires. Medicine will never serve the public properly if its practice is based upon the competition of specialists."

Choice of Medical Students—There was a general discussion of the selection of medical students. Medical schools are giving a great deal of attention to this subject. Medical students are selected for three things—first, intellect; second, character; and third, personality.

Dr. Sadlier said that he knew of a physician just now giving up a good and satisfactory practice in order to become a specialist and that he had tried and could not get any young man to go to the village where that successful practitioner had lived a number of years.

Dr. Hambrook observed that the need in medicine was to get the general practitioner back to his personal and intimate contact with the family.

Dr. Mitchell said that try as we may, it is not always possible to choose the best young man to practice medicine. Medical education has greatly advanced and we have no way of advancing education to the same degree in social and economic relationships. The social and economic status of the family is the important factor in medical care. Dr. Mitchell said that pre-medical training is a sort of screening process in the selection of the students of medicine. mittee on Admissions screens out a few more, and then the training in medical schools screens out a few more, and then finally the State drops off a few more. Dr. Mitchell said that he believed that humanity is better protected than ever in the history of mankind.

Health Survey-Dr. Sayer representing St.

Lawrence and Lewis Counties reported that the County Societies' Committees on Public Relations had worked on a survey of the county health, and the problem of tuberculosis among school children, and that no active work had been done other than that in some places a ray examinations of graduating classes would be done. The program of the Committees on Public Relations and Public Health had been submitted to the County Medical Society for apprival. In several coin

ties in his State health district he noted a new interest of physicians in their County Medical Societies

Speaking for Lewis County, Dr Sayer said that the nursing service had been abolished this year and that difficulties in the administration of the Lewis County state-aided hospital were being "ironed out" There is good cooperation with health officials in St Lawrence and Lewis Counties, but no cancer work was done

COMMITTEE ON PUBLIC RELATIONS

MEETING OF JANUARY 17, 1933

The Committee on Public Relations met in Syracuse at the Hotel Syracuse at 9 30 A M on January 17th 1933 There were present Drs Sadlier, Hambrook, Fisher, Cunningham, Mitchell, Johnson, and Ross, also, Dr Joseph S I awrence

Free Distribution of Cod Liver Oil—There was a long discussion regarding the free distribution of cod liver oil and the reaction of doctors to its distribution by health nurses, Red Cross nurses, or lay groups There was general approval of the free distribution of cod liver oil to children and adults when it had been prescribed by the physician in each individual case, but there was not approval of the promiseious distribution of cod liver oil by school physicians, by nurses, or by lay agents unless it was needed as a supplement to diet. This matter was brought up by Dr Iarrell. At the conclusion of the long discussion the opinion of the Committee on Public Relations was as follows.

"The free distribution of cod liver oil along with other food stuffs has given rise to some comment. This substance, so frequently thought of is medicine should be available and distributed if there is need of it in the diet. These are not normal times and liberal diets with wide choice of food stuffs cannot be made available for thou sands of our people. If for any reison the food supply must be restricted every effort should be made to have the amount and variety such as to avoid any immediate or future detriment to health. This responsibility rests with those in charge of food and distribution."

A communication was received from the Executive Committee of the State Society regarding a letter sent from the office of the Medical Society of the State of New York to the Governor with a copy to the Governor Elect, regarding the Governor's reference of the report of the subcommittee on medical problems to the Academy of Medicine, and called his attention to the fact that the Medical Society of the State of New York is the representative body of the medical

profession of the state and, therefore, the logical body to make recommendations and suggestions from a professional standpoint on problems that have to do with the medical aspects and adminstration of the Workmen's Compensation Act, with assurance that the Medical Society of the State of New York is willing and eager at all times to place its services at the Governor's disposal for the benefit of the State of New York This letter received the hearty approval of the Committee (Journal, February 1, 1933, page 169)

Climics in Factories—There was a long discus sion of the reference of a resolution received from the Council of the State Society regarding the matter of clinics in factories conducted by factory inspectors or others. It was decided to seek the advice of the officers of the State Medical Society before taking definite action.

The afternoon session was attended by all the members of the Committee on Public Relations and in addition Drs Larkin, Mitchell, Getman Groat Farmer, Flaherty, and Wynkoop of Syracuse Dr Lester of Seneca Falls and Dr Burns of Oswego

Dr Grint commented upon a readjustment of the expenses of the welfare department of Syracuse as an economy measure and stated that there had been no loss in efficiency, since an adult can be fed efficiently from \$1.10 to \$1.20 per week. The organized profession of medicine and the hospital dietitruis had been in great assistance in the administration of welfare relief in Syracuse.

Dr Turmer President of the County Society of Onondaga stated that his first object was to zet a strong Committee on Public Relations for the County Medical Society—men who had contacts with County Society problems and who would study the administration of the Public Welfare Law

Dr Farmer had a mild criticism of the SCAA in its apparently sponsoring a series of health institutes in the county. This should have been under authority of the County Society which

is ready to do this work, and he thought that this was a violation of the agreement with the S.C.A.A. in 1927.

Venereal Disease Control—There was some discussion and some criticism of the venereal disease program of the state. Dr. Sadlier of Dutchess County commended the work and said that a representative had activated the seventeen health officers in Dutchess County, particularly the eight health officers in the rural part of the county. It was brought out that there are forty-five venereal disease clinics in the State, most of them being in cities. The venereal disease clinic has been in operation in Poughkeepsie for fifteen years.

It was thought that no lay organization should undertake to lead in an institute on health when the County Medical Society could do it better.

Seneca County—Dr. F. W. Lester of Seneca Falls reported on the activities in his county. He said that they did not have any trouble with the S.C.A.A. He said that out of 4,968 days of treatment in the Seneca Falls Hospital, 1,098 days were paid for by private patients and the balance, 3,870 days, were paid for by public welfare or compensation. The County has a good Welfare commissioner who cooperates well with the

County Medical Society, and the County Society has a satisfactory cooperative relationship to the Board of Supervisors. All but two doctors in the county were members of the County Society.

Dr. Lester said that the health work in the county cost 25c per capita; that the County Society had studied the situation regarding a health department, modeling the plan on the plan of Cortland County and had concluded that \$18,000 would be a sufficient budget. The Society had not been able to establish a county health department because the seventeen health officers in the county had not been active in their support of the proposition.

Oswego Said that doctors of Oswego County will take up the study of the Welfare Law with the welfare officials. Formerly the City of Oswego had four doctors for the poor; now all the doctors are being paid for their work. The cost of welfare administration had increased in the city, and it was again proposed to have one doctor for the poor. The profession is now trying to settle the matter so as to have the physicians of the city do the work. He said that the hospitals are charging different rates. They should charge the per capita cost of \$4.50 per day.

LEGISLATIVE BULLETIN NUMBER 3

January 27, 1933.

No hearings have been announced as yet, nor has any action been taken on bills we are following.

NEW BILLS INTRODUCED

Senate Int. No. 365—Fearon; Assembly Int. No. 500—D. M. Stephens, to amend the Civil Practice Act by striking out provision if party to be examined in action to recover damages for personal injuries shall be a female, she shall be entitled to have examination before physician of her own sex. Referred to the Codes Committee.

Senate Int. No. 378—Cilano, to amend Chapter 798, Laws of 1931, relative to emergency relief administration to permit home relief for veterans and hospital care. Referred to the Finance Committee.

Senate Int. No. 426—Twomey, to amend the Education Law relative to sale of poisonous or habit-forming drugs or chemicals. Referred to the Education Committee. This bill includes barbituric acid with the habit-forming drugs.

Senate Int. No. 433—Crawford, to amend the Penal Law, providing hospitals supported at public expense shall not charge any fee for medical, dental or pharmaceutical services while operating clinic to which public is invited. Refererd to the Codes Committee.

Senate Int. No. 434—Evans, adds a new section to the General Municipal Law, for establishing a bureau in local public welfare or similar board, for supervising treatment of indigent ill. Referred to the Cities Committee.

Assembly Int. No. 395—Dickey, adds a new article to the Public Health Law, relative to habit-forming drugs, all acts inconsistent therewith being repealed. Referred to the Health Committee. Mr. Dickey has introduced the model drug bill that has been approved by the A.M.A. and sent to all states with the suggestion that it be substituted for whatever habit-forming drug law the state may have. We shall have copies of this bill available for any person who wishes to look it over, and we hope that we may have abundant advice regarding the action we should take. It is a very elaborate bill and should be studied carefully.

Committee of Legislation.

To County Society Legislative Chairmen:

Enclosed you will find the following bills:

Assembly Int. No. 328, by Mr. Close. This may not be of interest to many physicians, but it will have an informational value and it is primarily for that reason that we are sending it out. You will see that it provides that witnesses appearing before coroners or medical examiners

shall he paid the same as witnesses before any court. If it is of any interest to you, please give us your advice

Assembly Int No 329—Mr Cohen wishes to have a special study made of the Workmen's

Compensation Law

Assembly Int No 331-Mr Hayes includes

with the veterans, nurses who were attached to the regular Army as persons to have special consideration when seeking employment

Assembly Int No 342—Mr Messer's bill sumphfying the wording regarding those who should receive rehef under the Welfare Law

COMMITTEE ON LEGISLATION

LEGISLATIVE BULLETIN NUMBER 4

February 3, 1933

Action on Bills—Senate Int No 142—Berg, Assembly Int No 354—Rice, to permit restoration by regents of a license to practice medicine to a person pardoned after conviction of a felony, for insconduct in his professional capacity, has been reported out by the Education Committee in the Senate. You will recall our asking you in Bulletin No 2 for your reaction to this bill. If you are convinced it is a bad bill, it is important that you get in touch with your Senators at once and also register your opposition with the Assembly Education Committee, of which Mr. Rice is chairman

Hearings—February 7th—Assembly Int No 362—Bartholomew, permitting supervisors of a county not wholly in a city to terminate by two-thirds vote, all child welfare allowances in which ease the child welfare board shall be deemed abolished. Hearing before Assembly Judiciary Committee at 2 00 P. M.

Thus far the antivivisectionists, much to our surprise, have not asked for a hearing on either of the dog bills. The Assembly Codes Committee has announced its hearing calendar filled for the next

three weeks

New Bills—Senate Int No 456—Berg, to amend the Workmen's Compensation Law by providing compensation for any and all disabling diseases and disabling illnesses Referred to the Labor Committee

Senate Int No 487—Esquirol, Assembly Int No 705—Austin to amend the Public Health Law by providing Department rules and regulations shall be published at least once a week for two consecutive weeks, instead of six as at present Referred to the Health Committee The law at present demands that all rules and regulations relating to public water supplies shall be published in the local newspapers once a week for six weeks. This amendment is in the interest of economy and limits the number of times for publication to once a week for two weeks.

Senate Int No 604—Slater, Assembly Int No 780—Robinson, an amendment to the Criminal Code, providing that persons convicted of a violation of subdivision 4 of section 887, Code of Criminal Procedure, and found to be infected with

a venereal disease, shall receive medical treatment while imprisoned, and probation shall be granted only upon such terms and conditions as shall insure medical treatment of such disease and prevent the spread thereof. The law at present applies only to persons convicted in a city, the amendment deletes the words "in a city." Referred to Codes Committee

Senate Int No 622—Quinn, Assembly Int No 785—Robinson, to amend the Code of Criminal Procedure in relation to the inquiry into the insanity or mental condition of a defendant before or during the trial or before sentence. Referred to the Codes Committee. At present the law provides that a defendant may plead insanity, but the amendment, in addition to permitting this, would also give the court the right to interrupt a trial or delay pronouncement of sentence until after the examination of person, if the court is of the opunion there is a reasonable ground for believing that the defendant is insane. It provides for the appointment of a commission for the examining of the defendant.

Senate Int No 623—Quinn, Assembly Int No 784-Robinson, adds new section to the Mental Hygiene Law for certification of qualified psychiatrists by a board of examiners in Mental Hygiene Department Referred to the Health Committee This bill provides for the creation of a board of psychiatrie examiners composed of three persons, namely, the Commissioner of Mental Hygiene, the Commissioner of Correction and the head of the Department of Psychiatry of a medical college in New York State The board shall make its own rules and regulations and grant certificates to qual ified persons who must be physicians duly licensed to practice in New York State, with five years' experience in actual practice, and have had three years' full-time practice in an institution for mental defectives or have devoted five years to a practice confined wholly to the care of persons suffering from nervous and mental diseases

Senate Int No 624—Quinn, Assembly Int No 781—Robinson, to amend the Criminal Code relative to proceedings when a person in confinement appears to be insune or a mental defective Referred to the Codes Committee The amendment provides that if a person held in confinement appears

to be insane or a mental defective, the committing officer may commit such person to the care of a nearby state hospital or, in New York City, to the Department of Hospitals, for examination-and it found to be insane or mentally defective, treated in the same manner as if not held for a crime; if found to be of sound mind, to be returned to the original committing court. When a defendant charged with commission of a felony appears to the court of record to be insane, the court may, in its discretion, require an examination or observation of the defendant for a reasonable period; and if there is reasonable ground to believe the defendant is of unsound mind, he shall be examined by two physicians who shall have had a least five years' experience in actual practice and at least one of whom shall be a qualified psychiatrist, as provided by law. The report of the examination shall be submitted to the District Attorney or, if thought necessary, to a jury. The expenses of the medical examiners called as witnesses shall be paid by the county treasurer or by the comptroller of the City of New York, as the case may be, provided, however, the fees and expenses of the medical examiners shall not exceed in the aggregate the sum of \$200.00 each, unless there be a jury trial to determine the mental condition of the defendant, in which event there may be an additional allowance not to exceed \$50.00 per day for each day in actual attendance of the doctor as a witness.

Assembly Int. No. 692—Horn, to amend the County Law by providing no person not residing in Rockland County for at least three years, shall be admitted as a patient to Summit Park Sanatorium at Pomona. Referred to the Internal Affairs

Committee. Mr. Horn sponsored this bill last year.

Assembly Int. No. 772—Doyle, adds a new section to the Penal Law, regulating sale and manufacture of bichloride of mercury and compounds thereof and to prevent accidental poisoning. Referred to the Codes Committee. Mr. Doyle sponsored this bill last year and it was passed by the Assembly, but was not reported by the Senate Codes Committee. The Legislative Committee approved the bill last year; as a matter of record, it assisted Mr. Doyle in preparing the bill.

* * * * *

You have received from the Committee on Medical Research two pamphlets relating to antivivisection. More of these pamphlets are available and the Committee would be very pleased to have you give them to prominent lay persons. Such educational activity is very effective. Twice in the last week, Mr. Bernhardt has mentioned that he has been told by clergymen that this bill is bad. He now seems disinclined to urge further consideration of it and communications from prominent lay persons seem to have had greatest influence in bringing him to this decision.

We wish to correct a statement made in Bulletin No. 1 that Assembly bill Int. No. 102—Breen, is a duplication of the bill carried by Mr. Wallace last year, referring to the mistreatment of animals We were wrong; Mr. Wallace's bill was enacted into law. Mr. Breen's bill specifies a definite season in which it will be lawful to train dogs or hold field trials for game-hunting dogs. The point we want especially to emphasize is that this bill has no relation whatever to the antivivisection bills.

COMMITTEE ON LEGISLATION.

INTERNATIONAL GOITER CONFERENCE

The American Association for the Study of Goiter has arranged for a large representative American Delegation to go to the International Goiter Conference at Berne, Switzerland, August 10, 11 and 12th, 1933.

The Committee in charge of the trip has secured the low basic rate of \$215.55 for the round trip voyage from New York to Havre and return on the steamship *President Roosevelt*, with the privilege of returning on another vessel of the same line on the payment of an adjustment for the accommodations. The sailing date from New York is July 26th, and the ship should arrive in Havre on August 3rd, thus allowing a week of travel before the opening of the conference on August tenth.

A special feature of the going voyage will be a most attractive and educational round-table goiter discussion program. There will be daily sessions, each one of which will be conducted by some outstanding man.

A cordial invitation to join the delegation on the trip and participate in the sessions is extended to members of the medical societies of the States and Canadian Provinces. Proof of Society standing should accompany the formal requests for enrollment.

Applications for registration may be made to Dr. Martin B. Tinker, 404 Savings Bank Building, Ithaca, N. Y., who is the Geographic Delegate for the States of New York, Pennsylvania, Maryland and Virginia.

WASHINGTON COUNTY

The annual meeting of the Medical Society of the County of Washington was held at Hudson Falls, October 4, 1932, beginning at 4 p.m. and with 23 members present, as follows

Drs. Leonard, Borrowman, Vickers, Cuthbert, Samuel Pashley, Samuel J Pashley, Summer, Macarthur, Tillotson, Park, Ring, Davies, Casey, Bennett, Falkenbury, Heath, Prescott, Orton, Gillett, LaGrange, Holmes, and White

Visitors Dr James II Donnelly, Troy, Dr J W Stevens, Glens Palls, Dr Richard Kovacs, New York, Dr Carl Boettiger, New York, and G II IImey, DDS

The Treasurer reported \$115.26 in the treasury The following officers for 1933 were elected

President-Dr D E Macarthur

Vice President-Dr Roy E Borrowman

Secretary—Dr S J Brinker Treasurer—Dr C A Prescott

Censors—Drs S J Pashley, Jr, John Ring,

and C E Holmes
Chairman, Legislative Committee—Dr W A

Leonard

Chairman, Public Relations and Public Health Committee—Dr M A Rogers

Delegate to State Society-Dr D M Vickers

A motion was carried that our delegate be instructed to favor the passing of a law prohibiting the sale of fireworks on the fourth of July Dr Bennett presented the following resolution which was adopted "That this Society condemns medical radio advertising, and requests the State Society to follow up the matter in the American Medical Association, with the view of radically curtailing the vicious features of incidical propaganda"

Dr. Richard Kovaes read his paper on "Recent Developments in Physiotherapy," illustrated by lantern shdes The Doctor understands his subject and the paper was well received, and discussed

Dr John Ring read a paper on "Congenital Heart Disease," giving signs and symptoms for diagnosis and prognosis, of the different types

Adjourned for dinner

8 pm Dr Vickers, the President, gave as his address the prognosis and treatment of "Rup tured Gastric Ulcer" He gave the results of twenty cases at the Mary McClellen Hospital

Dr Carl Boettiger of New York gave his paper, "The Diabetic Patient and His Care" The methods used at the St Johns Hospital in Long Island City and the Mary Immaculate Hospital, Iamiica were described

Dr Boettiger and Dr Kovacs were given a vote of thanks

Meeting adjourned

S J BANKER, Secretary

ONEIDA COUNTY

An excellent account of the annual meeting of the Oneida County Medical Society, held on January 17, 1933, was printed in the *Utica Daily Press* of January 18 The following is an abstract of the report

"The meeting of the Oncida County Medical Society at Hotel Utica Tucsday afternoon demonstrated that the standing committees have been very active the past year. There were 45 doctors present who discussed the reports thoroughly and acted on most of them.

"Officers clected were President, Dr B P Allen Oriskany, vice-president, Dr L E Powers Ronie, secretary, Dr William Hale, Jr, treasurer, Dr H D MacFarland, librarian, Dr T Wood Clarke, censors, Dr W B Roemer, Dr B L Rockwell Oriskany Falls, Dr M D Graham, Dr E M Griffith, Chadwicks, Dr F M Miller, Jr, delegates to the House of Delegates, Dr G M Fisher, alternate, Dr Charles D Quinn, Dr Richard H Hutchings, alternate, Dr Dan Mellon, Rome

"Dr E M Griffith, the retiring president, spoke of doctors taking more interest in official

positions IIc cited the fact that Utica within a decade or two had doctors as mayors and they served well Doctors must fight vicious legislation at Albany each year. In the matter of health regulation doctors can wield a decided influence with their representatives. Doctors are in closer touch with the people and know their suffering and wants. The Legislature will heed the united action of the medical fraternity.

"Dr G M Fisher presented the report of the committee on costs of medical care. In it he says 'The medical profession asks for its practitioners freedom of opportunity to develop to the limit of their individual capacities. It asks a career of independence under conditions of free and dignified competition. It asks remuneration sufficient for reasonable comfort for the individual and for lus family. Medicine has a right to control its own affairs. Its history of capacity and altruism justifies this claim."

"Dr Halsey J Ball reported for the public health commuttee

"The report of the legislative committee was presented Dr Charles D Quinn offered this

which was adopted: 'That we repudiate the compensation practice of today; that we have a special legislative meeting in one month to decide on some plan whereby patient can decide whom he wishes to have treat him and to what hospital he wishes to go, with a governing board consisting of members from each hospital to decide on any

infraction made in the fee by the process of milking the insurance companies; and that the present contract method be abolished thus preserving the ancient policy of maintaining a close relationship between physician and patient.'

"Dr. T. H. Farrell reported for the committee

on public relations."

DUTCHESS-PUTNAM

The annual meeting of the Dutchess-Putnam Medical Society was held Wednesday, January 11, 1933, at the Hudson River State Hospital, Poughkeepsie, N. Y. The meeting was called to order by the President, Dr. William A. Krieger, at 8:50 p.m. Fifty-five members were present.

The following officers were elected for 1933:

President—Dr. Samuel E. Appel, Dover Plains. Vice-President—Dr. A. W. Thomson, Poughkeepsie.

Secretary-Treasurer-Dr. H. P. Carpenter,

Pouglikeepsie.

Associate-Secretary—Dr. E. Gordon Mac-Kenzie, Millbrook.

Delegate to State Society-Dr. C. Knight Deyo,

Poughkeepsie, 1933, 1934, 1935.

Alternate Delegate—Dr. Samuel E. Appel, Dover Plains, 1933, 1934, 1935.

Censors—Drs. A. L. Peckham, Scott Lord Smith, and C. V. Keating.

Counselor—Judge G. V. L. Spratt.

A questionnaire was read by Dr. A. W. Thomson, concerning sickness insurance and industrial medicine. Copies were ordered mimeographed and sent to each member.

The following report of the Cancer Committee was given by the Chairman, Dr. Helen L. Palliser.

"The Cancer Committee of the Dutchess-Putnam Medical Society submits the following report in regard to the educational activities which were undertaken after the appointment of the committee in April, 1932.

"In accordance with the plan submitted to this Society by your committee in June an intensive educational campaign was carried on during September and October and the early part of Novem-

ber. During the campaign a total of forty-four addresses were given, twenty-one in Dutchess county and twenty-three in the City of Pough-keepsie. The audiences numbered approximately 4,300. About six thousand pieces of literature were distributed, the literature being supplied by the American Society for Control of Cancer.

"Twelve local physicians participated in the campaign, and addresses were also made by Dr. John M. Swan, Executive Secretary of the New York State Committee for the Control of Cancer, and Dr. Burton J. Simpson, Chairman of the Committee. The Committee wishes to express its appreciation to all these physicians for their cooperation.

"We also desire to acknowledge our indebtedness to the Dutchess County Health Association and to the Poughkeepsie Committee on Tuberculosis and Public Health for their assistance and active co-operation in arranging the meetings throughout the county and city. Without this cooperation the campaign would have been a very

arduous as well as expensive task.

"Plans for the future were discussed and it was decided to complete the campaign by having addresses given during May in those districts throughout the county in which no addresses have yet been given on cancer. Tentative plans were also made to extend the campaign into Putnam County during the next fall.

"It is also recommended that a Committee be appointed in each hospital in the county in order to keep the cancer problem before our local physicians."

HELEN L. PALLISER, M.D., Chairman-JOSIAH COBURN, M.D. JAMES E. SADLIER, M.D.

KINGS COUNTY

The program of the monthly meeting of the Medical Society of the County of Kings, held on December 20, 1932, was as follows:

Address: "The Oldest Medical School in America," David Riesman, M.D., Philadelphia.

Address: "Tumors of the Thorax," George J. Heuer, M.D., New York City.

Presentation of a portrait of Dr. Ralph H. Pomeroy by Dr. Eliot Bishop. Unveiling by Wm. Sidney Smith. Acceptance for Society by Dr. E. P. Maynard, Jr.

The Bulletin of the Society says:

"Director of Activities—With December ends the first year of the experiment of establishing a

staff position, Director of Medical Activities, for the purpose of coordinating the possibilities of eooperative effort. At no time has the complexity of the problems confronting the community of which organized medicine is an integral and important part, been so great, the facilities to work with been so limited, the finances been so restricted.

"During this year, the County Society has maintained contact with the other neighboring counties of Long Island and the greater city, with the State Society officers and committee work, with the official departments of city and state, with the agencies engaged in health and welfare work-and with the public through radio, lecture and in-

formation service. "Cancer, diphtheria, child health, tuberculosis, venereal disease, diabetes, health centers, budgets, welfare relief, unemployment, nursing service,

medical care and other subjects have been considered.

"This involved, on the part of the Director of Medical Activities, more than 1,500 personal interviews with laymen and doctors in the Society office; over 3,000 telephone conversations; attendance at meetings requiring 500 day-time hours away from the building and an unmeasured amount of work in the preparation of material and correspondence."

The Endowment-The Board of Trustees announce the receipt of five thousand dollars from the estate of Dr. John Osborn Polak. In accordance with his wish and specific bequest, this sum has been placed in the General Endowment Fund in which he was so deeply interested, and which

he did so much to establish.

This bequest is the first large amount to be added to a fund, which, though new, must eventually become the most helpful and the most important of all our Society trust funds. Polak's generosity and confidence in the broader aspects of the work of our Society will help to make this possible.

The program of the meeting of the Medical Society of the County of Kings of January 17, 1933, was as follows:

hospital and dispensary problems, provision of

Inaugural Address: "Medicine-An Economic

Survey," John J. Masterson, M.D., Brooklyn. Address: "The Importance of Establishing a Conditioned Reflex (Pregnancy-Syphilis) in the Minds of the Medical Profession." Edward L. Keyes, M.D., New York City. Discussion by George W. Kosmak, M.D., New York City.

Presentation of a portrait of Dr. John O. Polak by Dr. Frank L. Babbott, Jr., and Dr. George Gray Ward. Unveiling by Dr. Alfred C. Beck. Acceptance for Society by Dr. Edwin P. Maynard, Jr.

The Inaugural Address of Dr. John J. Masterson, the President, dealt principally with methods leading to a solution of the economic problems facing the medical profession. "I believe that the sine qua non for the solution of many of our problems will be found in an efficient administrative body, backed by a united profession. I have no objection to the organization of any group outside our rank. But I am also of the opinion that in organized medicine, as exemplified in the County Society, we have the strongest body at our command to work out our local problems. I believe the five county societies should replace our coordinating committee with a permanent Medical Council, or Medical Business Bureau, call it what you may, having a full-time working personnel, and headed by a high class Medical Prime Minister, as it were, who would also devote his entire time to the Bureau. Let this be the body to whom

our city-wide problems may be referred for definite action after we have carefully studied a question and made our recommendations."

The Bulletin says:

Medical Relief .- The provision of medical relief through city departments and unofficial agencies has begun to operate. Physicians are being called upon to render medical relief and asked to realize that the original plan worked out a year ago was based upon the principle of treating illness at home where that would be more satisfactory than hospital care. Obviously the sick member of a family receiving relief in the form of food, rent, clothing and the like, needing medical care for serious long-term illness, such as pneumonia, contagious disease and the like, requires hospitalization.

Examination of High School Students.—The Co-ordinating Committee of the Five County Medical Societies has discussed the proposed plan for the examination of high school students unable to pay the private physician. The Committee on Public Health has also been studying this subject. It is expected that a uniform plan may be worked out through the Co-ordinating Committee whereby each county society will undertake to supervise and provide the examination of those high school students who are unable to obtain the required examination from a private physician. In this connection the practitioner of medicine is urged to examine all students in his private office and fill out the form provided for this purpose and give it to the student for presentation to the high school.

MONROE COUNTY

The annual meeting of the Monroe County Medical Society was held on December 20, 1932. The following officers were elected to serve during 1933:

President-Dr. J. P. Henry. Vice-President—Dr. Sol J. Appelbaum. Treasurer-Dr. John J. Rooney. Secretary—Dr. William A. MacVay.

The following appointments were made:

Committee Chairmen Public Health-Dr. E. G. Whipple. Legislative—Dr. L. F. Simpson. Post-Graduate Instruction—Dr. S. S. Bullen. Speakers—Dr. B. J. Duffy. Public Relations-Dr. A. G. Morris. Periodic Examination—Dr. S. J. Appelbaum. Nutrition—Dr. C. B. Gibbs. Membership-Dr. E. H. Burnes.

Sub-Committee Chairmen

Tuberculosis—Dr. J. J. Lloyd. Cancer-Dr. J. M. Swan. Child Welfare—Dr. John Aikman. Nervous and Mental-Dr. G. Kirby Collier. Health Education—Dr. W. A. Sawyer. Heart-Dr. R. B. Crain. Social Hygiene—Dr. F. J. Garlick. Communicable Disease—Dr. G. S. Price. Maternity Protection—Dr. L. E. McCaffrey.

The January News Bulletin of the Society contains the following extract from Annual Report of the chairman of the Public Health Committee:

"The Committee has established cooperative re-

lationships with the Rochester Health Bureau, the Tuberculosis and Health Association, the Public Health Nursing Association and the Rochester Dental Society; is represented in the Council of Social Agencies; and has been in conference with Hospital Superintendents, Town and Village Health Officers, and representatives of the State Department of Health.

"It has sponsored a diphtheria immunization program for preschool age children in the County area outside of Rochester, and has conducted educational activities to safeguard child health against threatened epidemics of measles, scarlet fever,

poliomyelitis and smallpox.

"Through the Heart Committee, a second survey of 100 High School students found in the Health Bureau Medical Inspection to have possible heart disease was made. A systematic follow-up of cardiac cases was recommended. The use of Type Classification in cardiac diagnosis including recording of Etiological, Anatomical, Psysiological and Functional Findings was recommended.

"Since the radio broadcasting program was initiated in May, 1930, 135 different physicians and 22 dentists have given talks. It has been necessary to mimeograph more than 48,000 copies of these talks to meet the demands of the radio audience and others interested. There has been a newspaper follow-up in the Monday morning Democrat and Chronicle of every one of the 120 broadcasts. At the present time there are more than 200 copies of the broadcast loose-leaf covers in physicians' offices and dentists' waiting rooms, and they are in constant use in the public libraries, the medical school, public schools, and the offices of health and welfare agencies."

SUFFOLK COUNTY

The first regular meeting of the Suffolk County Medical Society since quarterly meetings were authorized, was held in Roe's Hotel, Patchogue, on Thursday, January 26, 1933. Forty members assembled for a noon lunch, after which routine business was transacted, and the scientific program was carried out.

Dr. Louis F. Garben of Islip, who had been elected Vice-President, was advanced to the presidency, owing to the death of the Presidentelect, Dr. J. H. Marshall, last November.

Dr. Morley B. Lewis, Sag Harbor, was elected

Vice-President.

There was a lengthy discussion on the economics of the practice of medicine in Suffolk County, with tentative suggestions that the Society might form a credit or collection agency; but no action was taken.

The scientific program consisted of two papers on the reports of two national committees that are receiving wide attention by both the medical pro-

fession and the people.

Dr. William H. Ross, of Brentwood, read a paper on the report of the Committee on the Cost of Medical Care, dwelling especially on the manner in which economic and social conditions in a village or town affect the practice of medicine in that community. Doctors are already familiar with many phases of community action in medical practice, such as the care of the indigent and the control of contagious diseases. It will be to the interest of physicians to make an impartial study of the findings and recommendations of the Committee on the Cost of Medical Care, and to criticize them constructively rather than destructively.

Dr. Frank Overton of Patchogue gave a

twenty-minute informal address on the Report of the Committee on Medical Education, talking from an outline which was shown in a series of forty lantern slides. Dr. Overton discussed the points of view of five medical surveys of interest to every doctor in Suffolk County.

1. The report of the New York State Health Commission, which discussed the political aspects of the practice of medical administration, especially that by departments of health. It offered county health departments as a great step forward.

2 The report of the Committee on the Costs of Medical Care, which dealt with the economics of medical practice, and suggested group action as a solution of the economic problems in medical practice—the group to consist of

actice—the group to consist of

(a) Physicians in hospitals as medical centers (b) Guilds or insurance groups by the people

3 The report of the Commission on Medical Education, which dealt with the psychological and scientific phases of medical care, and emphasized the education of family physicians as an essential basis in the delivery of adequate medical care to the people. The report further suggested that each group of doctors study the needs of its own community, and devise additional methods to meet those needs.

4 The report given at the annual staff meeting of the Southside Hospital in Bryshore. This hospital is essentially a medical center for the 40 000 inhabitants of the southwest corner of Suffolk County and the forty doctors who practice there. The chiefs of each of its several departments outlined the needs of the community in that department of medical practice, and made suggestions for sipplying those needs. The reports constituted an excellent survey of medical practice in a semi-rural community, whose people are rated generally as fairly well to do

5 A survey of medical practice in Suffolk County to be made by the physicians themselves Each physician is the family doctor to a group of from 100 to 300 families and can give information regarding each one as regards the economic, social, and intelligence standing of its members, their need of medical service, and their acceptance of it, their needs of service beyond that received.

and their patronage of cults and quacks

The physicians were asked their reaction to such a survey of their own practice. While no formal action was taken, the sentiment of the doc tors was favorable to the plan. It was understood that an outline of procedure for making the proposed survey should be devised and submitted to the Society at its ownterly meeting in April

EDWIN P. KOLB, Secretary

MEDICAL ECONOMICS A CENTURY AGO

Group insurance for medical care existed one hundred years ago, as is shown by an agreement found by Dr Wickham F Case of Center Moriches, Suffolk County, among the papers of his grandfather, D W Case of Patchogue, who was one of its signers

"The undersigned heads of families and residents of Patchogue and its vicinity desirous of having a phisician resident amongst us whose character as a man claims our respect and in whose professional skill we have confidence and being well acquainted with Dr Wm S Preston and believing him worthy our confidence as a phisician and respect as a citizen do hereby contract with said Win S Preston to officiate as our family phisician for the term of two years from the seventh day of June one thousand eight hundred and forty, for which service we do each of us prom ise to pay annually for two years as above written in four equal quarterly payments to said Wm S Preston the sums set opposite our respective names in witness whereof we have hereunto set our hands this sixteenth day of May one thousand eight hundred and fort;"

This paper was signed by 39 householders, who subscribed \$557 annually Dr Preston practiced medicine in Patchogue for sixty years until his death in 1897, aged 87 years

Some thirty or more years previously a similar paper had been circulated in Patchogue, in which a number of householders had subscribed \$200 annually as a gift to Dr Nathaniel Miller of Brookhaven, in order to keep him from moving away to a more promising field of practice, but no one seems to have acted as collector, and the only person who paid up was the village innkeeper, who always paid his subscription of five dollars

Dr Miller had received his original license to practice from the Suffolk County Medical Society in 1807 This license was reproduced in this Journal of Tebruary 1, 1931, page 164

THE DAILY PRESS

Mr. and Mrs.-

From the New York Herald Tribune, January 30, 1933.

VITAMINS

Man is monarch of all creation by virtue of conquest. He takes by force that which lower creatures produce, and gives them little credit for their work. This bit of philosophy may have

been in the mind of James J. Montague when he wrote the following verses in the section "More Truth Than Poetry" of the New York Herald Tribune of January 20th:

Essay on Man

The codfish lives his lifetime through Providing food for me and you; He's caught and dried And boiled and fried Our breakfast board to victual; And though his liver, lungs and fins Are simply filled with vitamins Which buck and brace The human race,

They help him very little.

Tomatoes, underneath their skins, Supply no end of vitamins, Which they convert From garden dirt To furnish forth man's uses. And if he rose before the dawn
And labored till the sun was gone,
He could not count
The vast amount
The spinach plant produces.

It seems to be great nature's plan
To make existence soft for man,
And yet he'll whine
When bright suns shine,
And wish that it was raining.
Although with all good things supplied,
The fellow's never satisfied;
The whole world's his,
And yet he is
Eternally complaining.

SURVEYS

The medical profession, like all other groups of persons, is subjected to all sorts of surveys. Doctors will agree with the following editorial in the New York *Times* of January 22:

"Today half of the world would seem to be engaged in surveying. People go about it in truly monarchic fashion. They dispose of mighty issues and huge rows of figures with a sweeping Louis XIV gesture. But there the comparison stops. Surveyors behave like monarchs, but they are not treated like monarchs. Instead of there

being nobody their right to dispute, there are plenty of critics. Half the world is engaged in surveying and the other half is engaged in challenging the surveyors.

"And what does it lead to? It leads to more surveying. This last week has seen the beginning of at least one attempt to survey a survey; and other demands for the right to survey said survey are pouring in. If these surveyors in the second dimension should happen to disagree with the first surveyors, then it is plain what will follow. The

friends of the original survey will demand a thorough survey of the second survey. But in that case the thing will never end, it will go on ad infinitum, you say Oh, no It will end all right,

and quite soon It will end as soon as the public gets tired of the whole business, and there are signs that the public is getting tired at the rate of ten million horsepower a day"

245

THE FAMILY DOCTOR

The New York Herald Tribine of January 7 used the inaugural address of Dr. Bernard Sachs as President of the New York Academy of Medicine to make the following plea for the family doctor

"Dr Sachs deplored the general practitioner's development in recent years of something like an inferiority complex and said. The general medical diagnostician, the man with broad vision, with calm judgment, with the human touch—the family physician—with the full appreciation of the needs of the individual under the present strain of social and economic stress, is sorely needed."

'Changes in medical practice,' says the Lowell report on nicdical education, 'lave not and can not modify the essential unit of medical service and training, which is the patient. And the in changing patient is a sick, and therefore unduly sensitive, human being who is not only under in spection, as a watch or a boiler might be, but who

has the doctor under as close and critical examination as the doctor has him. What the head of a family wants of a doctor is a thoroughly trustworthy friend who will take the members of the family under his unremitting care when they need it, and not an expert inspector who will refer each of their ailments to a different high priced stranger for impersonal treatment

"Forty per cent of the graduates of medical col leges now become specialists and half of these have no experience in general medical practice. The reason for this, as the Lowell report points out, is that specialization is easier and more profitable. Such views as Dr. Sichs has expressed have the support of all the leading medical organizations in the country, but it is the laity that has to convince the family doctor that these are its sentiments if the propaganda for impersonal medical care is to be silenced and if the best men are to be attracted to general practice."

LIFE IN METEORITES

The New York Herald I ribine of February 2 discusses life in meteorites and fossils in the following editorial

"Professor C B Lipman's announcement of living bacteria believed to have been found in side meteorites which reached the earth from outer space would be of extraordinary importance for theories of evolution and of life's origin could it be accepted unqualifiedly. There are, however, grave reasons for skepticism For some five years Professor Lipman has been testing rocks and other materials for supposedly ancient germs in side them These have been found he believes, in ancient sedimentary rocks, in anthracite coal at least 200,000,000 years old and in crude petroleum from the wells To this list now are added the meteorites The case would be stronger were it less perfect-had similar materials been tested with equal thoroughness and found not to harbor living organisms. The very ubiquity of these finds makes one suspect that the germs are slipping in somehow through a chink in the methods

of sterilization So far as we know, only one group of Professor Lipman's tests has been repeated by another expert These were the tests on coal, from which repetition Professor Homer G Turner, of Pennsylvania State College, found no proof of any germs except common living species which may have entered the coal through tiny cracks

"This is something which might have happened to all of the specimens, even the meteorites. Certain bacteria are known to possess tiny life forms, so small as to be quite invisible. All rocks and similar materials are somewhat permeable to water. There is every reason to imagine them also permeable to the timer varieties of life germs. Only a meteorite found immediately after its fall, wrapped in some sterile germ proof covering and then sibmitted successfully to Professor. Lip man's tests could be considered really strong evidence. Life germs are so widespread in the air, the clouds, the soil and every where that even this would scarcely be conclusive."

BOOK REVIEWS

CHILD CARE TODAY. By BÉLA SCHICK, M.D. and WILLIAM ROSENSON, M.D. 12mo of 320 pages. New York, Greenberg: Publisher, [c. 1932]. Cloth, \$2.50.

The strongest impression made on this reviewer by Dr. Schick's book is the standardization of modern life.

In all essential particulars, the reviewer or any other pediatrist whom he knows, might have written much as Dr. Schick has except for the words he chose; but the words, and the ideas expressed by them regarding physical care and mental management, are well chosen.

Any criticisms therefore would be on trifling matters rather than the important items. Certain materials, it seems to this reviewer, were included because of the writers' enthusiasm for them, for instance, who would recommend to any mother, except by direct personal advice, a butter-flour formula; and of course Dr. Schick's intimacy with the charming and capable Pirquet almost demanded the inclusion of the "nem" though the reviewer thinks it of no small value to a mother.

The book can be recommended as another good guide W.D.L.

for mothers.

NURSES ON HORSEBACK. By ERNEST Poole. Octavo of 168 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$1.50.

The organization and work of the Frontier Nursing Service in isolated regions of the mountains of Kentucky have been told by Ernest Poole in his book, "Nurses on Horseback," written after a visit to that region. He tells of the adventurous spirit and the willingness to suffer hardship of these pioneer nurses, and of their courage and indomitable will, believing no matter how difficult hopeless even—a situation may appear there is a way out of it.

The individual trips taken with members of the staff in fording swollen rivers, "over winding mountain trails, up rock creek beds to the gaps and down steep treacherous paths," and carrying injured and sick patients on horse or mule back for treatment, are beyond the everyday aspect of the average layman and nurse and are so far removed they seem like life on another plane.

Seven years ago the organization of the Frontier Nursing Service was started by Mary Breckenridge with two nurse-midwives working from one center. The author tells of the rapid growth during these years with twentyeight nurses now in the field and three supervisors working from eight centers and covering nearly eight hundred square miles. Mrs. Breckenridge said "nearly eight thousand people, most of them women and children, are in our care, and we serve about fifteen thousand in all in various ways from time to time," and this is accomplished by the "nurses on horseback." "Only the ablest women carefully trained are adequate" for the service and the nurse is tried for six months in Kentucky and if acceptable sent for midwifery training.

The author tells of the work done by the nurses during the "Great Drought" and the famine; of the continual fight against hookworm, tuberculosis and typhoid. There are many pictures showing the stoicism, endurance and faith of the mountain women in the face of suffering and privation that no woman should be called upon to endure, and showing a heritage and strength of character not met with in the experience of many nurses.

"Nurses on Horseback" is picturesque, dramatic and fascinating; should be read by all nurses and would prove a thrilling tale to doctors and social workers.

GERTRUDE R. SMITH.

THE HEART RATE. By ERNST P. BOAS, M.D., and ERNST F. GOLDSCHMIDT, Ph.D. Octavo of 166 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1932. Cloth, \$3.50.

In 1928, E. P. Boas designed an instrument, the cardiotachometer, with which to record the heart beats continuously during periods of work, sleep, rest and play. This monograph presents the deductions of himself and co-author, E. F. Goldschmidt, based on a study of 356 patients of the Montehore and Mt. Sinai Hos-

Considering that the very first watch with a second hand was not made until 1665, it is not surprising that the pulse rate per minute was not determined for many years. Sir John Floyer in 1707 had a special watch made for his studies, but not until the early 1800's was much clinical data reported on. The Chinese had established the normal pulse—respiration rate of 4-1 to 5-1, but pulse rates in relation to disease were not cited in medical writings before the ease reports of Graves, Louis of Paris, Allan Burns, Nick, Bruillaud, and Stokes in the period of 1808-1854.

Such a book as this is necessarily filled with tables and charts, but also there is spread on its 166 pages much interesting clinical data. As the pulse rate could be determined at any time and under any and all conditions, the text, chapter by chapter, records the heart rate during sleep, during activities of the day, during

anesthesia and operations, and in disease.

In a brief review, these various pulse rates cannot be quoted in toto, but we should know that the basal pulse rate was determined as 61 for men and 69 for women, thus substantiating the findings of Sutliff and Holt in The basal rate was determined at rest, in the early morning before breakfast.

Fatigue, nervous tension, anxiety, and emotions all tended to increase the pulse rate, even in subsequent sleep, although sleep, as such, was found to lower the rate. Restlessness and loud noises, even a thunder storm, elevated the rate during sleep, thus constituting an argument for quiet sleeping quarters. In day naps, the rate did not drop as during night sleep.

In women the pulse rate is at its lowest level during The highest rates in men and women menstruation. were observed during sexual orgasm. These observa-tions, like many others in the volume, have a practical value to clinicians. FRANK BETHEL CROSS.

COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION. Vol. 23, 1931. Edited by Mrs. MAUD H. MELLISH-WILSON and RICHARD M. HEWITT, M.D. Octavo of 1,231 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$13.00.

Of these, 99 Papers written in 1931 numbered 577. are reprinted in full, 36 are abridged, 43 are abstracted, and of 399 only the titles are given. As stated in the Foreword, the aim in selecting the material for this volume has been, as in previous years, to produce a work which would be useful to the general practitioner, diagnostician, and general surgeon. For this reason, many papers, important in themselves, but mainly of interest to specialists in some branch of medicine, surgery or pure science, have been included only by abstract or

by title.

The papers are classified under gross anatomical divisions, with a chapter devoted to Technic and to Miscellaneous Subjects. There is a complete bibliographic index and an index of subjects. Such a volume includes a wide range of discussions with the most recent of

opinions on the subjects considered. It represents the Progress of Medicine, not only from the viewpoint of the workers at the Mayo Clinic, but from that of medicine in general. This volume will astonish the easual reader and delight the many Mayo enthusiasts.

J. RAPHAEL.

NURSING IN NERVOUS DISEASES. By JAMES W. Mc-CONNELL, M.D. Octavo of 153 pages, illustrated. Philadelphia, F. A. Davis Company, 1932. Cloth, \$1.50.

The contents of the book are the substance of a series of conversational clinical lectures delivered to classes of curses at the Philadelphia General Hospital. The author was prompted to write the book by the knowledge that nursing the organic neurological patient was an extremely important subject with which pupil nurses must become familiar. He found that most nurses' text books did not cover that phase of ill health, and generally the subject was given but a few limited pages in books on mental illness. He has written an excellent little book, covering the most important types of neurological disorders in the chronic neurological wards.

IRVING T. SANDS.

PSYCHOLOGY IN GENERAL NURSING. By ISABEL G. II. WILSON, M.D., D.P.M. 12mo of 216 pages. New York, Longmans, Green & Co.; London, Edward Arnold & Co., 1931. Cloth, \$1.60.

The book is based mon a series of lectures given to nurses. It is a practical little volume, worthy of consideration for any group of pupil nurses. There is a vein of common sense and practical facts mingled with really scientific data. The more modern approach to medical psychology is covered in a very concise and yet thorough manner. The book is written in a style that is both appealing and instructive, and is a valuable addition to the large number of nurses' text books.

IRVING J. SANDS.

HANDBOOK OF THE VACCINE TREATMENT OF CHRONIC RHEUMATIC DISEASES, By H. WARREN CROWE. Second edition. Octavo of 79 pages. New York, Oxford University Press, 1932. Fabrikoid, 80¢.

One of the easiest things in medicine is to provide an hypothesis, however fanciful it be, and then to institute a method of treatment based on this supposition. One of the fallacies of medical practice is to swing from one extreme to another when an existing system of therapy is not reaping its expected results. That the theory of focal infection is not working out so accurately in actual practice is continually coming to our attention. Instead of looking at the facts in a straightforward manner and admitting our shortcomings we are beckened to accept other procedures which are often as unsound in theory and as unsuccessful in their results.

The writer of this book is "more and more coming to the conclusion that foci of infection should it possible dealt with after and not before the treatment of the disease by vaccines." He also tells is "hat the removal of a focus may so stir up the condition or debilitate the patient that it renders later treatment very difficult and much more prolonged." The reader must surely take notice when he claims that "between 80 and 90 per cent received benefit." It is improper for one physician to fatly disparage the work or the report of another. We depend too much on the element of time which so mellows criticism as to make it seem almost praiseworthy.

THE CHEMISTRY OF TUBERCULOSIS By H. GIBEON WELLS, M.D., Ph.D., and ESMONN R. LONG, M.D., Ph.D. Second edition, revised. Octavo of 481 pages, illustrated, Baltimore, Williams & Wilkins Company, 1932. Cloth, \$7.00.

This is a highly authoritative volume written by two

of the most prominent research workers and investigators in this particular field in America. Highly technical in character, its appeal is necessarily to a rather limited clientlee, but to those few a most valuable and indeed indispensable presentation. Every director of a bacteriological laboratory will soon have this on his shelf not far from his chow.

FOSTER MURRAY,

Bony Mechanics: Education and Practice. Report of the Subcommittee on Orthopedics and Body Mechanics, Robert B. Osgood, M.D., Chairman. White House Conference on Child Health and Protection. Octavo of 166 pages, illustrated. New York, The Century Company, (c.1932). Cloth, \$1.50.

This is a report of the investigation made by the White House Conference on Child Health and Protection, into the relation of the body mechanics and posture of the health and well-being of children; Dr. R. B. Osgood being chairman of the special subcommittee.

The report includes the investigation of what is now being taught about body mechanics, and an analysis of statistics as to the incidences of poor body mechanics in children.

General recommendations are made on how the incidence of poor body mechanics in children may be lowered; it now being very high throughout the population of the United States.

The Committee recommends the use of the term "Body Mechanics," instead of the term "Posture," and defines Body Mechanics as "The mechanical correlation of the various systems of the body, with special reference to the skeletal, muscular, and visceral systems, and their neurological associatious. Normal body mechanics may be said to obtain when this mechanical correlation is most favorable to the function of these systems."

The book contains a wealth of information. It should be read by all interested in physical education, and particularly those who teach physical training in medical schools; schools of physical education, public, parochial, private schools, etc.

J. B. L'Eriscoro.

A TEXT-BOOK OF PATHOLOGY. An Introduction to Medicine. By William Boyd, M.D. Octavo of 946 pages, illustrated. Philadelphia, Lea & Febiger, 1932. Cloth, \$10.00.

The third book on Pathology written by Boyd has superseded the expectations foreshadowed by his offerings of Surgical Pathology and the Pathology of Internal Diseases.

Beginning with the preface, which is a masterpiece of expression of what pathology really stands for today, to the end of the book it is replete with information founded upon actual lahoratory experience. Seldom has it been the pleasure of the reviewer to be overcome with the desire to read a book from cover to cover. In this instance, the desire has been transformed to actual performance. The work is well classified and presented in such a manner that both the medical student may understand and remember the information and the pathologist may secure much material for thought.

The inclusion of discussion of relation of symptoms to lesions is so well done that it scarcely needed the explanation for its presence in the preface.

The reviewer is tempted to write of the many nice things which this book contains but fears that they are too numerous to mention. An occasional item of criticism might be mentioned, such as the misquotation of Connheim's theory and the rather loose manner of speaking of infection in relation to cancer. The English is in the author's usual entertaining, interesting and pleasant style. All in all the reviewer can find no book which is to be so heartily recommended to the student, general practitioner and pathologist. It is well worth including in the library of any medical man.

M. Lenerer.

OUR NEIGHBORS

ANNUAL REGISTRATION IN TEXAS

The Texas State Journal of Medicine for January has an editorial discussion on the results of the annual registration law of Texas. After discussing the lack of classification of the records of licenses, the article says:

"What this means may be appreciated when we consider that 8,621 licenses were issued to doctors who claimed to have practiced medicine in Texas prior to 1907, when the present Medical Practice Act was enacted. Of this number, 226 were listed as Eclectics, 134 as Osteopaths, and 82 as Homeopaths. The licenses of the Regulars, Eclectics and Homeopaths came from three separate boards that existed at the time. The records of the Osteopaths were accumulated at the time, under the provisions of the new law. Since that time, 8,621 have been licensed. The Directory of the American Medical Association for 1931 showed 6,475 practitioners of medicine in this State. The Board has transferred all of these records from several books to a single large book, so prepared as to show all of the data called for under the present Medical Practice Act. There were 15,560 of these. The book will hold 50.000 individual records.

"In addition to these records, there have been compiled complete files of 1,250 medical crooks. fakers, fake scientists and health lecturers, imposters and swindlers of a large variety having to do in some way with the practice of medicine, practitioners of medicine who have been outlawned in this and other States because of violation of narcotic and alcoholic laws and certain criminal activities, not to try to mention all of the possibilities in the field of criminal quackery. Through the use of these files, incidentally, a number of fakers have been caused to desist from their activities in this State, some of them quite precipitately. a knowledge of how to go about this sort of thing and with the full cooperation of the medical profession on the spot, the State Board of Medical Examiners can prevent much financial, physical and mental injury of the unsuspecting public by such conscienceless imposters. Many of our readers will recall seeing the display advertising of some of the wonderful lectures on health subjects,—even, be it said to the shame of school boards, in the auditoriums of some of our public schools. The activities of the State Board in this connection has resulted in a widespread sentiment of support among our prosecuting authorities and our courts, not to mention newspapers, chambers of commerce, better business bureaus and the like.

"There are those who have expected the State Board to run all of the illegal practitioners, quacks and cults out of the State forthwith and immediately. No such thing was possible, of course, nor was any reasonable approach to it expected. The record is good enough as it is, and not to be complained about. It will show that during the past year there have been 40 convictions of violations of the Medical Practice Act and 8 acquittals. Eighteen licenses have been revoked. Eighty-five cases are now before the courts, and 220 under investigation. During the year, a representative of the Board helped to arrest itinerant fakers who were, it has been estimated, taking from \$150,000 to \$300,000 per year out of the State. A notorious group of swindlers, claiming to be eyesight specialists, have been apprehended, very largely by the investigator for the State Board, and brought to punishment in other States, where opportunities for heavy penalties were greater than they were in Texas. This group swindled one Texas woman out of \$7,400.00 by pretending to remove a cataract from her eye. The investigator for the Board, through his individual and unaided efforts, captured two leaders of a dangerous criminal gang who were operating in Texas, and returned them to other States for prosecution. They are both now in the penitentiary. In addition, an undetermined but relatively large number of practitioners, held to be practicing either without sanction of the law, or engaging in practices which lay them liable to prosecution, have been induced to leave the State in order to avoid prosecution. The certificates of some of these have been taken up and the Board has the certificates in its possession, together with releases signed by the individuals concerned."

SURVEY OF HEALTH AGENCIES IN MICHIGAN

The Michigan State Medical Society has a special committee which is making a survey of all health agencies, both medical and lay in the State of Michigan, as has been described

in this Journal of December 1, 1931, page 1480, and February 15, 1932, page 246. A progress report on the survey is contained in the De(Continued on page 250—adv. xiv)

cember, 1932, Journal of the Michigan State Medical Society. The major part of the report refers to the slowness of physicians to respond to the questionnaire. The report says:

"With certain exceptions public relations committees have been appointed by the local societies and have supplied the necessary information preliminary to the local studies. In certain cases no replies have been received from the secretaries of these societies; and in one case the public relations committee appointed has been inactive. Since these societies include sixteen counties it means that we now have returns from sixty-seven of the eighty-three counties in Michigan."

The Journal gives a table showing the responses of individual physicians. There were 3,386 blanks mailed, of which 1,233 were returned. The percentage of physicians responding ranged from a maximum of 60 in some of the smaller counties to only 29 for the largest,—Wayne, in which the City of Detroit is located. The report continues:

"Following the original plan, lists of those physicians who have failed to return a schedule have been mailed to public relations committees of local societies. These committees are asked to designate the approximate incomes, within very broad limits, of each physician who has failed to make a return. While these figures will not be included in our analysis they will serve the purpose of determining whether or not those who failed to cooperate are to be found largely in only one income group.

"The study of population and income is now making good progress and should be completed before January 1. This study is regarded as fundamental to the committee's final conclusions and must form one of the major pillars upon which the recommendation will rest.

"The study of public health agencies has reached the stage where practically all of the material has been collected and the major part of this material has been analyzed for presentation. At present the report on these activities is being prepared and will be presented to the sub-committee for its consideration approximately December 1. The recommendations from the sub-committee will be transmitted with the report to the state committee

"The sub-committee on hospitals is now revising the main hospital schedule and the collection of information will start about November 15. In addition, data are now being prepared concerning the governmental expenditures for hospitals in Michigan. These expenditures will include the hospitals for mental diseases, tuberculosis, and other communicable diseases.

"As soon as the studies of physicians and

(Continued on page 251-adv. xv)

(Continued from page 250—adv. xiv) hospitals are completed, the remainder of the studies will be brought to a close rapidly, so that the committee may begin to draft its conclusions at an early date. According to the present plan the committee will start its regular sessions during the early part of December. The task of digesting the information will be a tremendous one and the value of the entire series of study will very largely depend upon

CRIPPLED CHILDREN IN ILLINOIS

the time permitted for this process.'

The December number of the *Illinois Medical* Journal contains the following report of the commission on physically handicapped children ap-

pointed by the Legislature:

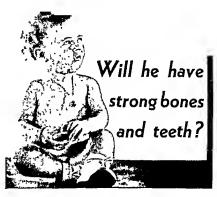

"Pursuant to Joint House Resolution number 20, adopted by the House, March 21, 1929 and concurred in by the Senate, May 21, 1929, wherein was designated as a commission, the Director of Public Welfare, the Director of Public Health and the Superintendent of Public Instruction to report to the Fifty-seventh General Assembly its findings and recommendations pertaining to the conditions of the Handleapped children of Illinois, their hospitalization, their education and all other facts pertinent to their welfare, the Commission begs to submit the following report:

"The Commission wishes to acknowledge its obligations to the fine spirit of co-operation of those helping to make the survey throughout the State. In each county a local commission consisting of three members was appointed, one by the Director of Public Welfare, one by the Director of Public Health and one by the Superintendent of Public Instruction. Usually the County Superintendent of Public Schools, a social worker, if one was available, and a physician of repute made up the county commission. The local commissions worked through school teachers, social workers, fluress and physicians and others who were available.

"Sixty-four counties made fairly thorough surveys, thirteen made partial surveys and twenty-five made little or no response Ten thousand nineteen children have been listed with their addresses, ages, school attendance and a probable diagnosis. When the partial and non-reporting counties have made their reports the number of children will exceed twelve thousand. It is also evident that there will be five thousand others who have not been located. This will bring the total number of handicapped children in the State up to seventeen thousand.

"The percentage of crippled children under twenty-one in this State has been figured conservatively at 22 crippled children to each one thousand of the general population. This average was taken from the listing of eight of the well worked counties Williamson County, however, has only 1.8 crippled children per thousand of

THE INDIGENT IN NEBRASKA

The medical care of the indigent is discussed in the following editorial in the January number of the Nebraska State Medical Journal:

"Press reports indicate a willingness of an increasing number of county boards to assume responsibility for the medical and surgical care of indigent persons, which is very encouraging. A hitch seems to develop in some cases over the basis of payment and on this matter there seems wide divergence of opinion that threatens agreement. Taking rural Nebraska for example-In one county the county medical society offered to take care of paupers and indigents on a basis of \$3.00 per call, plus mileage, other work in proportion; in another county the county board offered to pay on a basis of \$1.00 per call. This is a rather wide difference and probably both parties would be willing to some modification of the suggested basis.

"Let us not forget that we are in a period of economic stress the like of which none of us has ever experienced; that county boards, willing though they may be to pay, are hampered by shortage of funds due to the inability of the taxpayer to meet his obligation to the county and state; that when county boards agree to a willingness to assume the financial obligation of medical and surgical care of pauper and indigent, the

financial reward is certain and half a loaf is bette than no bread. In other words, it is better to work for a smaller fee sure to be paid, than to get nothing."

The same journal prints another editorial re lating to the Board of Supervisors of Holt County and says:

"What the Holt county profession thinks abou it is evidenced by the following resolutions presented to the county board at a recent meeting:

"Resolved, that \$2,336.00, which is the total amount expended in Holt county for medical hospital, and nursing fees is a very nominal sum Of this amount \$1,700.00 is the total amoun spent for medical fees. Thus the per capita ex penditure in Holt county, which has a populator of 16,000, is about 10 cents per head. An addi tional \$636.00 was expended for hospital and nurses fees in the care of the poor. Thus the per capita expenditure for medical, hospital and nursing fees is less than 11 cents per head.

"Be it resolved, that when a physician calls: inember of the county board regarding medica attention to an individual or family unable to pa and the county commissioner agrees to accept th case as a county medical or surgical charge that he issue an order to the doctor granting authorit for such treatment, said order to accompany th

doetor's claim to the County Board, the same to be paid without further argument providing the charge is in conformity with those established by these resolutions."

"The following is the medical fee schedule for Holt county and now enforced:

"House visits, \$3.00, plus mileage.

"Confinement, uncomplicated, \$25.00 plus mileage. Additional charge for complicated eases.

"The county board has refused to pay any medical bills whatever."

SOCIAL MEDICINE IN NEBRASKA

The Nebraska State Medical Journal for January contains the following editorial comments on social medicine and contract practice:—

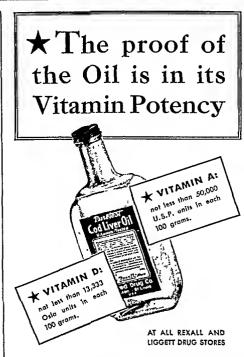

"After attending the secretaries' and editors' conference in Chicago the 18th and 19th of November it is evident to us that we in Nebraska have little first hand knowledge of contract practice. The extent to which it exists in this state has not made a notable impression on us as it has in most other states.

"The program of the three sessions was almost wholly devoted to contract practice and to state medicine. No more interesting meeting was ever held, but the net result was an adjournment without arriving at any concrete plan of attack to the disappointment of many of those present.

"The problem is very complex. Some of the outstanding propositions advanced were: Outside of the industries 405 groups are offering contract service in the United States. Contract practice as such is not unethical unless freedom of action of the individual affected, is disturbed. The patient has the inalienable right to choose his physician. Diagnostic laboratory groups have overreached the physician. They should not compete with the physician-they should assist him. Laboratory diagnosis has been over-emphasized. training must be reemphasized and diagnosis made much more simple and at less cost to the patient. We have indulged in a debauch of hospital construction with too many stately columns and marble halls and useless glitter, and have forgotten the needs and financial capacities of the white collar man.

"The Georgia plan of regulating contract practice appealed strongly to many delegates. Physicians desiring to engage in contract practice submit their plan to the censors of the county society for their approval and by conference between the parties the objectionable features, if any, are removed before the plan is approved. This plan is said to work very well in Georgia and is worthy of consideration in other states.

"It seems to this writer that social medicine is upon us and that some of our energies should be enlisted toward its direction rather than to adopt the tactics of the Pope's Bull against the Comet."

WHEN you prescribe end liver oil for pregnant mothers and for babies, it is because you know they need Vitamin D to build strong, straight teeth and bones.

When you prescribe it for run-down children and adults, it is because you know they need Vitamin A to build resistance against infections.

Since cod liver oil is effective only in proportion to the amount of these two vitamins it contains, isn't it just good practice to make sure that your patients get an oil which contains the greatest possible amount of them?

Note above the content of Puretest Cod Liver Oil in Vitamins A and D. This rich vitamin content is always stable because it is protected from deterioration caused by oxidation. Before the containers are filled with oil, all air is forced out by filling with nitrogen gas.

Protect your patients by specifying a cod liver oil which is of guaranteed vitamin potency and moderate cost—Puretest Cod Liver Oil.

Vol. 33, No. 5

NEW YORK, N. Y.

March 1, 1933

MEDICAL SOCIETY OF THE STATE OF NEW YORK ANNUAL REPORTS, 1932-1933

REPORT OF THE PRESIDENT

To the House of Delegates:

ientlemen:

With the convening of this House of Delegates here has passed another year in the history of ie Medical Society of the State of New York, he Society year of 1932-1933 will probably stand i historical perspective as the end of an epoch nd the beginning of a new era. The social forces hat have been germinating for the last twenty ears and reached their apogee shortly after the Var period were bound to produce fundamental ffects in the social condition of our people and pon the medical profession. With the tremenous accumulation of wealth, derived from the atural resources of our country and the superlaive development of industrial machinery, it is not urprising that large sums of money were betowed for the purpose of creating foundations hat were interested in social progress. The genral wealth and well being of the people attained uch a degree of prosperity that an university ducation became the common or habitual amation of most of the households of this country. There resulted from this a huge influx into our miversities, with a tremendons number of young people anxious to enter the professions.

In 1900 there were 160 medical schools. There are at the present time 66, giving a standard four-ear course. Yet it is interesting to note that the 66 schools now graduate 5,700 doctors a year, which is equivalent to the number of graduates urned out in 1900. The reason for this is that while the population from 1890 to 1930 increased 15 per cent, the admissions to colleges for acalemic degrees increased over 770 per cent. To-day there are about 16,000 applicants for bout 5,700 medical matriculations, so that approximately 10,000 boys per year are tmable to enter a medical school.

There is in the State of New York one doctor to approximately 620 of the population and in the United States probably 156,000 physicians, and yet this tremendous number of physicians consti-

tute only 10 per cent of the people who are engaged in the national health program, so that fully nine times as many more individuals who are not doctors are engaged in some form of other in a medical or health program and these individuals must of necessity be coordinated into the health activities of the country.

The year just passed has been significant in a variety of ways, and in particular by the publication of the reports of various commissions, committees, foundations, social uplifters, philanthropies, social reformers, and others too numerous to mention. Obviously, some of these reports were frankly critical of the medical profession and not a few represented a determined attack upon the quality and distribution of medical services in this country. A few were definitely protagonists and advocates of full and complete state medicine and believed that a medical Utopia would be produced by the State becoming a medical colossus and directing all curative and preventive medicine. It became necessary for your Executive Committee to receive these various reports, criticisms and pronunciamentos, and submit them to careful, deliberate, critical analyses. This policy has been followed in regard to the two major reports and the result of the deliberations of the special committee of your members will be presented to you.

The continuing, deepening economic depression necessarily reacted upon the financial competency of our members and the majority of the members of this Society have had varying degrees of difficulty in obtaining a fair financial return for their services during the recent depression years. The financial disability of our members in the large cities has, in many cases, been acute and by reason of the very tenuousness of renumeration in the private practice of medicine it would seem that our profession suffered disproportionately in comparison with other professions of similar degree of attainment.

Every component society has had a number of

its members unable to pay their State assessment. There has arisen from this a desire to both lessen the dues and to memorialize this House of Delegates for a reduction in the per capita, per annum Your Executive Committee were assessment. deeply sensitive to this condition of affairs and recommended to the Board of Trustees that there be disbursed to the component societies an amount of money equal to one dollar per member as of June 1, 1932; the funds of your Society have been wisely invested and it was possible to declare, so to speak, a dividend out of investment income. The purpose of this allocation of funds to the component societies was to enable them to devise a method whereby their delinquent members, temporarily financially embarrassed but loyal to the Society, could be financed on part payment basis. In my opinion, this was a wise step. It indicated that the State Society, by reason of superior managerial ability, high capital income, could invest and create investment income quite beyond the resources of the local society. It is axiomatic that the directional capacity of your Society is primarily determined by the caliber, character and ability of the men you elect to office. I believe it is also axiomatic that in the final analysis the activity of your Society will be expressed by a composite of the intelligence of its members. Granted, however, a wise policy and competent effective officers, there are still required funds to maintain your Society. In addition, the last three years have demonstrated that an organization or institution without cash reserves is in such an unstable and weak financial condition that it might fail from inability to sustain itself during a prolonged financial depression. It should be the object of this Society to create the power for proper medical service, and to safeguard their members in the distribution of medical service. To do these things it is more and more essential that your investment fund, instead of being \$125,000 should be at least \$250,000 and possibly \$500,000. The income from such a fund would provide the revenue necessary for a more complete fuller business administration.

The problems before medicine to-day are not alone the problems of medical treatment, but are the problems of the contacts of the medical profession with a highly mechanised society. What was originally the main desideratum of medical societies, namely, the practice of medicine, has become only one aspect of a tremendously intricate problem of medico-social adjustment. Aside from the salaries of secretaries and the maintenance of a competent office staff almost the entire work of your Society is based upon the voluntary labor of your Officers. Judging from the experience of your retiring President this embraces such an tion if in the near future your Society will not, of necessity, need more paid executive assistants. amount of detailed work that it is a serious quesAll great institutions are the lengthening shadow of a personality and this House of Delegates was the reflection of a very distinguished gentleman. Few of us realized that when this House met a year ago in the City of Buffalo that the Speaker of the House, Dr. John Card, would be called away before this House convened again It is fitting that your President should record in his report the obligation this Society owes to the labors, personality, and the judicious temperament of the late lamented John Card.

Considerable progress was made in the simplification of your executive structure in the con solidation of the Committee on Physiotherapy and on Periodic Health with the Committee on Public Health and Medical Education under the Chairmanship of Dr. T. P. Farmer. It is believed by most competent medical pedagogs that medical education is a continuing and continuous process and that your Society has but started upon a larger program of itineraries of graduate medical instruction. Thoughtful students of graduate instruction believe that this type of instruction should be brought to the doctor in his own environment and the possibilities for this formal activity upon the part of your Society are indeed promising.

During the past year the administration of the Workmen's Compensation Law has been subject to a survey by a special commission appointed by the Governor of the State. The abuses in the administration of this type of medical service have been great and the professional and ethical turpitude of some of the physicians giving this service has been appalling. Your Executive Committee. early in the year, asked the Committee on Economics, under the Chairmanship of Dr. Charles II. Goodrich, to make a study of the medical and professional aspects of this question. The result of their deliberations will be presented to you for your study and consideration. In this connection your Society, together with the Academy of Medicine of New York, jointly requested the Governor of the State of New York to appoint a medical committee to make a complete study with the ob ject of amending or changing the law in order that the grave abuses of commercial clinics would be obviated.

In an era of financial depression one is impressed with the amount of projected social legislation. Well intentioned individuals, on seeing a condition that by and of itself is depressing, immediately proceed to ask for legislation and as many of these prospective legislative acts concert themselves with medical practice or with social service it has been necessary for your officers to be ever on the alert in anticipating socially bad legislation or measures that are distinctly an invasion into the field of the practice of medicine. The Legislative Committee, under the Chairman ship of Dr. Harry Aranow, and the Committee on

Medical Research, under the Chairmanship of Dr Frederic E Sondern, assisted by the Executive Officer, Dr J S Lawrence, have been particularly zealous in anticipating such legislation and in marshalling the proper forces to expose its defects

This forthcoming 127th Annual Meeting of your Society will demonstrate the remarkable scientific work of the membership and the complete manner in which the scientific program his been arranged by the Committee on Scientific Work under the Chairmanship of Dr Arthur J Bedell We are beholden to the Medical Societies of the Counties of New York, Brons, Kings, Queens and Richmond for their very warm well come for this meeting in the City of New York and in like measure to the Committee on Arrange ments under the Chairmanship of Dr Samuel J Kopetzky

During the last year there has been a tendency for certain component societies to initiate certain movements within their ranks without due regard for the State Society Every physician must look upon the medical profession in the State of New York as one organized whole and any policy that is in the slightest manner divisive to that extent diminishes the prestige of the Society Medicine, both organized and individual, is under eriticism and there is a spirit manifest throughout the country to place most of the social burdens of medical practice upon the medical profession. The medical profession are in no way responsible for the lessening of the national income from 82 bil lion dollars in 1929 to 37 billion dollars in 1932 We are, however, very much concerned with the fact that one third of the physicians in this country are living on a gross income of less than \$2 500 a year, and that 50 per cent of the doctorof this country gross \$3,500 a year or less per We are disturbed by the fact that 65 per cent of the people of the United States own but 15 per cent of the wealth of the country and that two per cent of the people own 40 per cent of the total wealth of the country We view with apprehension the fact that about 85 per cent of the peo ple of this country subsist on incomes of less than \$2,000 a year

We have grave doubts about the value of the extension of individuals into the domain of medicine and view with alarm the crippling of society with a health incubus of bureaueratic control when it is amply demonstrated that mass production in indicine cannot be applied to such discased conditions as Nephritis, diabetes, and cardio vascular disease. We may well question the wisdom of the instituble governmental activities in social service based upon a false premise of the infallibility of statistics and the irrefutable validity of surveys. The cost of social service exclusive of education to day represents one-fifth or more of the total expense of our cities, and in one of the most enlightened stries.—Massachusetts

—the cost of this service represents nearly two fifths of the total outlay by the State —The cost of State government has increased per capita from \$3.97 in 1913, to \$16.38 in 1929, and the cost of city and local government per capita has increased from \$19.10 in 1913 to \$58.64 in 1929. In this field the Committee on Public Relations under the Chairmanship of Dr. James E. Sadler have contributed significant and distinctive services.

One out of eleven of our membership are be ing, or will be sued for malpractice and if there is any one particular function of this Society that must be preserved intact, under resolute and forceful administration, it is legal defence and malpractice protection It seems to your President that as a means of creating a united medical front and medico-legal solidarity, defence and indemnity should go hand in hand and that legal de fence by the Society should be withdrawn from those members who insure in companies other than the official carrier of the Society To be long to the Medical Society of the State of New York is a high privilege and we should be zealous in the maintenance of an esprit de corps and an organized front against any and all invasions into our particular field of social usefulness

Fundamental economies have been made in the management of your funds. Your Trustees and your Treasurer have been unrelenting in the safe guarding of your investments and the control of your funds. A perusal of the report of the Treasurer will show significant reductions in the expense of your major activities.

Without the ever valuable help and experience of the Secretary, Dr Daniel S Dougherty, and the fine spirit of cooperation by the Assistant Secretary, Dr Peter Irving, together with the aid given by Miss Baldwin and the staff at the So ciety's offices in New York City, the duties of your President would have been arduous in the extreme. Your President takes this opportunity to express his great personal appreciation for their many kindnesses and their willingness to help him at all times.

Your retiring President feels that the year just past has been all too short for some of the many projects that press forward for solution. He would have liked to have attempted more and to have completed more but he is happy in the thought that in the midst of universal gloom, financial depression, poverty and the breaking down of personal and social integrity the Medical Society of the State of New York has been true to its history, accepted its traditions and carried them forward with added lustre and prestige

Respectfully submitted,

CHAS GORDON HELD, President

February 15, 1933

REPORT OF THE SECRETARY

To the House of Delegates: Gentlemen:

Your Secretary has the honor of submitting his eighth annual report.

He has in former reports stressed the fact that the office of Secretary is an executive one rather than merely clerical and as yet nothing has occurred to induce him to change his opinion.

When the House convenes and faces the Speaker's chair, it will no longer look into the happy, genial face of its Speaker, for he who presided over its destinies during the past few years is no longer with us. The Society has sustained a great loss and will miss his intelligent, carnest and enthusiastic leadership. To all of the officers and members who came in contact with Dr. John A. Card this loss has been felt as a personal one, for his kindly character had endeared him to all.

The Secretary suggests that the members of the House rise and stand in silence as a tribute to his memory.

THE SOCIETY

It is a matter of congratulations that despite the prevalent business depression the Society has held its own both numerically and financially as can be seen from the statistical report. The membership has dropped but very little compared to this time last year and even this decrease may be discounted when we consider that last year's report included the figures to May 1st whereas this year ends with March 1st.

Owing to rumors that the membership and income of various so-called "up-state counties" have been considerably diminished, your Secretary made a thorough investigation into this situation and he is pleased to be able to report to the contrary.

Six of the county societies have raised their dues and everywhere there are indications of an increased interest in organized medicine, not only among the members but among those who have not as yet availed themselves of the privilege. Requests for application blanks are more numerous than ever and even at this early date several societies are almost 100% paid up.

Nor has there been any let-up in the strenuous and excellent work of the officers and committeemen.

The Secretary is pleased to note that the Special Committee appointed by the 1932 House of Delegates to further cooperation and coordination of activities has presented a report entirely in consonance with the report of the Secretary under date of April 15, 1928, which states, "that there exists today an almost harmonious co-relation of all the elements and component units that com-

prise the corporate body, a considerable lessening of the overlapping and encroachments of the duties of officers and committees and a sincere cooperation of all toward the upholding of the ideals and purposes of the Society."

THE SOCIETY'S OFFICES

There has been no change during the past year in the personnel of the office force. The same competent, willing and obliging staff continues its excellent work under the direction of Miss L. D. Baldwin whose efficient management, wonderful grasp of details and knowledge of the Society's affairs past and present are of incalculable value, not only to the Secretary but to the Society in general.

LEGAL DEPARTMENT

Of this department suffice it to say that our counsel, Mr. Lorenz J. Brosnan, has continued to prove himself worthy of every confidence reposed in him. Apropos of this, it would be well to cite the incident of a lawyer who, having called on your Secretary as Secretary of N. Y. County for assistance in a certain case, made the plea "that he was up against one of the brightest and shrewdist trial lawyers in the state".

CONFERENCES AND DISTRICT BRANCHES

Owing to illness your Secretary was able to attend but four of the District Branches and for the same reason was unable to attend the Conference of Secretaries in Chicago. While he regrets all of these enforced absences he very keenly regrets not being able to participate in the Chicago meeting as the reports show a complete change of feeling and an acceptance of the views expressed by him at several of the former conferences.

The attendance and enthusiasm at the District Branch meetings were on a par with those of several years past and the programs were of considerable worth. Comment should be made here of the Tristate Conferences which have twice presented important and timely topics for discussion.

REPORTS AND COMMUNICATIONS

The Secretary renews the plea of former years regarding the necessity of devising some plan whereby the work of the Reference Committees could be so handled as to expedite the business of the House and of avoiding the rushing through at the last moment of reports and resolutions without giving them proper attention and discussion. The old and unbusinesslike custom of submitting last minute reports to the Executive Committee still prevails despite the fact that three Houses of Delegates have adopted a resolution

requiring that they shall be in the limids of the Secretary at least 48 hours before the meeting of the Body for which they are intended. Attention is also called to the importance of having all reports and communications go through the limids of the Secretary with the exception of those which should more properly be sent to the Legis lative Bureau.

The Secretary extends his sincere thanks to those officers members and employees for the sympathy and support expressed in various ways during his illness. It was indeed fortunate that he had such a willing, able and efficient assistant as Dr. Peter Irving and that the President, a man of sterling worth, keen judgment, earnest and euthusiastic, with an insight into the problems that confront the profession granted but few, resided in New York City where he was in constant intimate touch with the husiness of the Society

To Dr Irving he extends his sincere thanks, to the President he owes his thanks for many acts of kindness and friendship and a debt of gratitude that can never be repaid for his prompt action in bringing him home when taken ill up the state, an action which probably saved his life

He thanks the Executive Officer for his sup

port and cooperation

*It is of much interest to note that in spite of the depression there are only about two hundred more de linquents than last year which number will be materially decreased by the time of the Annual Meeting as 1932 dues are being received daily

The list of honor counties is as follows Allegany, Cattaraugus, Chenango, Fulton Madison, Scholarie Seneca, Tioga and Tompkins

Respectfully submitted,

DANIEL S DOUGHERTY, Secretary

February 15, 1933

REPORT OF COUNCIL

To the House of Delegates Gentlemen

The Council has the honor of presenting the following annual report which includes those of its Executive Committee Committee on Publication and Committee on Insurance

In accordance with Chapter IV of the By Laws the Council convened in the Hotel Statler, Buffalo, May 24th, 1932, for the purpose of or-

ganizing for the ensuing year

Physiant to the provisions of the By Law governing the constitution of the Executive Commit tee, the following members of the Council nominated by the President, were elected to serve with the officers therein specified as said Executive Committee John A Card, Arthur J Bedell, Charles D Kline, Loms A Van Kleeck, and James M Flynn

The appointment of members of the Standing Committees was referred to the Executive Committee

Dr Frederic E Sondern was appointed Chair man of a Special Committee on Medical Research with power to nominate members of the Committee who need not necessarily be members of the Society

A regular meeting was held at the State Society rooms, New York City, on December 8th, 1932

Dr Flaherty, Chairman of the Special Committee appointed in accordance with the resolution of the House of Delegates to further cooperation and coordination of activities and make the collective thought of the State Society effective and powerful, reported

'That no further action was necessary as a study of the work of the State Society amply demonstrated that there is already a wonderful cooperation and coordination between the Committees through whose activities and contact with Medical and Lay Organizations the collective thought of the State Society is becoming more and more influential and powerful."

Arthur W Booth was appointed Chairman, James T Rooney Nathan B Van Etten, George W Cottis Saminel J Kopetzky, Charles H Good rich and Edward E Haley, members of a Special Committee to study the Report of the Committee on the Costs of Medical Care and the Report of the Commission on Medical Education and report to the House of Delegates—Owing to the resignation of Dr Van Etten, Floyd S Winsley was appointed to fill his place

James E. Sadlier was appointed to draw up resolutions on the death of Dr. Card to be pre-

sented to the House of Delegates.

Alec N. Thomson was appointed the President's special representative to go to Detroit and study the Detroit Plan of Medical Participation in Public Health Work.

EXECUTIVE COMMITTEE

The Executive Committee has held regular meetings on the second Thursday of each month, at the first of which it organized by electing Chas. Gordon Heyd, Chairman, and John A. Card, Vice-Chairman. At this meeting, Orrin Sage Wightman was appointed Editor-in-Chief, Frank Overton, Executive Editor, Lorenz J. Brosnan, Legal Counsel and Thomas H. Clearwater, Attorney; also as Publication Committee, John A. Card, Daniel S. Dougherty and Frederic E. Sondern; as Committee on Budget, the Speaker, the Secretary and the Treasurer.

Much of the business transacted during the year has been necessarily of a routine character, the Committee acting as Council ad interim being essentially the business and administrative body

of the Society.

Although the work of the Executive Committee is routine, it is extremely important and the Committee has at all times given serious consideration to the many important problems which have been brought before it.

As a detailed report would be unnecessary waste of time and space, only the more important

decisions and actions can be mentioned.

Under date of June 16th, the annual budget submitted by the Budget Committee was approved and ordered submitted to the Trustees.

The renewal of the contract with the Executive Officer was approved and referred to the

Trustees.

The following nominations of committee men were made by the President and endorsed by the Committee:

Scientific Work-Frederic E. Sondern.

Public Health and Medical Education—George W. Kosmak, Mahlon H. Atkinson, Leo F. Schiff. William A. Groat, Martin B. Tinker, Clayton W. Greene, Edward G. Whipple and Nellis B. Foster.

Legislation—John J. Buettner, Bernard B. Berkowitz, B. Wallace Hamilton and Edward E. Haley.

Arrangements—Samuel J. Kopetzky, Chairman.

Medical Economics — Frederic E. Elliott, Joseph P. Garen, Frederick M. Miller, Homer L. Nelms, Joseph C. O'Gorman, Cassius H. Watson, Terry M. Townsend, Frederick S. Wetherell and Edward R. Cunniffe.

Public Relations—William H. Ross, George M. Fisher, Oliver W. H. Mitchell, Augustus J. Ham-

brook, William D. Johnson and Thomas H. Cunningham.

Medical Research—John Wyckoff, S. R. Detwiller, George Baehr, G. Canby Robinson, Augustus B. Wadsworth, Edwin MacD. Stanton, Herman G. Weiskotten, John J. Morton, Jr., Winfield W. Scott, Burton T. Simpson, F. A. Hartman, James L. Gallagher, Simon Flexner and Peyton Rous.

Insurance Committee—John A. Card, Chairman, and Frederic E. Sondern.

Prize Essays-Henry H. M. Lyle, Chairman.

Martin Cohen and Joshua E. Sweet.

Press Publicity—Alec N. Thomson, Chairman, Edward C. Podvin, James N. Vander Veer and Louise W. Beamis.

To Prepare a History of Medicine in the State of New York—Frederic C. Curtis, Nathan B. Van Etten and Alvah S. Miller. Owing to the inability of Dr. Curtis to act, Dr. Ross was appointed in his place.

John A. Card and Frederic E. Sondern were appointed to act as a Special Committee to consult with the Saratoga Springs Commission in its effort to develop the mineral water resources of

Saratoga Springs.

James N. Vander Veer was reappointed Liaison Officer to act with the State Department of Health in the campaign against Venereal Disease.

The Executive Committee also passed a resolu-

tion:

"Appropriating from its investment surplus to each County Society a sum equivalent to One (\$1.00) Dollar per capita as of July 1st, 1932, which action is in no way to be considered as de-

termining or establishing a precedent."

Under date of September 8th, Dr. Frederic E. Sondern was appointed Chairman of the Insurance Committee and the Committee on Publication, and Vice-Chairman of the Executive Committee to fill the vacancy left through the death of Dr. Card. Louis A. Van Kleeck was appointed a member of the Insurance Committee and James E. Sadlier of the Executive Committee.

Frederick H. Flaherty was appointed ex-officion member of the State Charities Aid Association's Committee on tuberculosis. Dr. Flaherty later resigned and the President was granted permission

to act in his stead.

It was decided to hold the next Annual Meeting at the Waldorf-Astoria Hotel, New York City, on April 3rd, 4th and 5th, 1933.

Under date of October 13th the Committee went on record as endorsing the Special Bond Issue for New York State to provide aid for the unemployed.

Some doubt having been expressed as to the resolution passed by the last House of Delegates concerning the division of fees, the Legal Counsel's advice was sought as to whether this might not be in conflict with the Principles of Profes-

sional Conduct—The Counsel's opinion was that it constituted an extremely dangerous precedent and was repugnant to and in conflict with the meaning and purposes of Section 32 of the Principles of Professional Conduct.

Under date of November 10th a resolution was passed:

"That the Insurance Company should investigate all complaints, errors or accusations regarding malpractice defense received by them in writing."

In accordance with Section 1265 of the Medical Practice Act, Martin B. Tinker, James E. Sadlier and Frederic E. Sondern were nominated to fill the vacancy on the Grievance Committee left through the expired term on December 31st, 1932, of Dr. Tinker.

Under date of January 12th the following rules governing Malpractice Defense and Group Insurance prepared by the Insurance Committee were approved by the Executive Committee and referred to the House of Delegates for endorsement,

RULES GOVERNING MALPRACTICE DEFFNSE AND GROUP INSURANCE

MEMBERS NOT INSURED UNDER THE GROUP PLAN

The Medical Society of the State of New York will furnish to its members the services of the Counsel of the Society in actions brought for alleged malpractice, error, or mistake done or claimed to have been done in the legitimate performance of the duties of their profession as physicians under the following regulations:

The Counsel of the Society will serve as attorney in all actions for alleged malpractice, brought against members in good standing, who must be so certified by its Secretary, excepting as follows.

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed prior to their admission to membership in the State Society.

Members shall not be entitled to malpractice defense if the acts in the suit for which they make application for defense were committed during a period when they were not in good standing, according to Chapter XIV, Section 4, of the By-Laws.

Members shall not be entitled to malpractice defense while residing and/or practicing medicine or surgery outside of the territorial limits of the State of New York.

The Society will not undertake the defense of any member who, after consideration by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide, or any criminal act or who has not complied with the recognized ethical laws in regard to these cases.

Members shall agree not to compromise any claim against them, nor to make settlement in any manner without the advice or consent of the Society given through its attorney.

In the event that a member sued or threatened with suit shall, without the advice or consent of the attorney of the Society, determine to settle or compromise any claim against him, he shall reimburse the Society for the expense incurred in undertaking his defense, and in default thereof, he shall be deprived of further privilege of malpractice defense.

The Society shall not assume any responsibility for the payment of any sum agreed upon by arbitration in the settlement of claims, or awarded by court verdicts, or for making payments for any purpose whatsoever.

Members of the Society desiring to avail themselves of the privileges of this act shall make application therefor in writing to the Secretary of the Society, and it shall be shown to his satisfaction that they are members in good standing. They shall also furnish the Legal Counsel a complete and accurate statement of their connection with, and treatment of, persons upon which complaints against them are based, giving dates of attendance, names and residences of nurses and of other persons cognizant of facts and circumstances necessary to a clear and definite understanding of all matters in question, and shall furnish such other relevant information and execute such papers as may be required of them by the attorney of the State Society.

In the event of any difference of opinion between a member of the Society and the Counsel concerning the eligibility of a claim for defense, or any other matter having to do with inalpractice defense or indemnity, all details shall be presented to the Insurance Committee to be referred with recommendations to the Executive Committee of the Council for its decision.

The foregoing regulations are subject to such a change as may from time to time be authorized by the Executive Committee of the Council or the House of Delegates,

MYMBERS INSURED UNDER THE GROUP PLAN

All members in good standing shall be entitled to malpractice defense and indemnity in the Group Plan of Insurance on payment of the premium due on the policy selected but the amount of insurance protection granted to any member may be limited at the discretion of the Executive Committee of the Council, subject to petition for reconsideration.

If an assured shall fail to maintain in good standing his membership in the State Society, according to Chapter XIV, Section 4, of the ByLaws, the policy, so far as it applies to such assured, shall be cancelled as of the date upon which he ceased to be a member in good standing. A notice to this effect shall be mailed to the member's last address, and the Company will return upon demand and surrender of his certificate, the unearned premium due him on account of such cancellation. If the member is reinstated by payment of dues, the former policy cannot again be put in force but the member can secure a new policy under the same conditions as if he were a new member of the Society. This rule shall become operative if and when it is written into the policy of the Group Plan.

The Group Plan of Insurance shall insure a member within the limits of his policy against loss growing out of suits or claims for malpractice, error or mistake, committed or alleged to have been committed by an insured member in the legal practice of his profession or by any assistant of such a member, in the treatment or care of a patient previously seen and diagnosed by such a member and for whom the member has directed

a course of treatment or care.

The Group Plan of Insurance shall not cover the liability of an insured member on account of the use of x-ray for therapeutic treatment, the employment of partners, associates, assistants, technicians or nurses to practice medicine in his name independently of his personal diagnosis and specific instructions as to the treatment or care to be given, nor shall it cover the liability which such a member may have by reason of his participation in or ownership in whole or in part of any association, partnership, clinic, hospital, sanitarium, dispensary or any enterprise other than his private practice of medicine. The liability for such participation or ownership constitutes additional hazards not contemplated under the Group policy or rates, and losses on account thereof shall not be charged against the experiences of the Group Protection against these hazards shall, upon request and the payment of an additional premium, be furnished by the carrier by endorsement upon member's Group Plan Certificate or under an additional policy of insurance when

The Group Plan policy shall not cover the liability which an insured member may have on account of injury to patients from causes other than medical treatment, care or advice, nor for injury to persons other than patients from any cause whatsoever. Protection on account of such losses can only be had under general liability or workmen's compensation insurance.

When in the course of duties imposed upon him as a medical officer of the State, or any political sub-division thereof, an insured member shall be required to render medical opinion, he shall be fully protected under his Group Insurance against the consequences of such an opinion pro-

vided it shall have been given to competent authority and not made public by him.

All members in the Counties in Greater New York and Rockland, Westchester, Nassau and Suffolk, desiring insurance protection in the Group Plan of the State Society, shall secure that protection through the Authorized Indemnity Representative of the Society, Mr. Harry F. Wanvig.

MEMBERS INSURED BY COMPANIES OTHER THAN THE CARRIER OF THE GROUP PLAN

A member who elects to secure malpractice insurance protection from a company other than the Carrier of the Group Plan shall have the same right of defense by the Counsel of the Medical Society of the State of New York as those members not insured provided said carrier is authorized to do business in the State of New York. If the member desires this service under the circumstances, all the regulations as detailed above applying to members not insured under the Group Plan must be observed. At the time the action is begun and not later the Secretary of the Society shall be furnished with the name of the Insurance Company, policy number, date of policy and amount of insurance carried. There shall also be presented at the same time a letter from an authorized officer of the Insurance Company certifying that the Company will assume the full cost of the defense including the fees of the Counsel of the Medical Society of the State of New York similar to those paid by the Carrier of the Group Plan in like instance. Also that he shall not be required to consult with or receive instructions from the Company as to the manner of defense and that the Company will accept his opinion on the final disposition of the action.

As Companies other than the Carrier of the Group Plan usually compel the holders of their policies to accept defense by the Legal Counsel of the Company concerned, the above would not apply. It is essential, however, that members so insured shall also enjoy the benefits of the services of the Counsel of the Medical Society of the State of New York if desired but it is obvious that such service will be restricted by the rule of the Insurance Company cited above. Thus while the Legal Counsel of the Medical Society of the State of New York cannot be required under these circumstances to assume control of the defense or to appear as associate counsel, he shall be ready to render to the Counsel of the Insurance Company, if requested, a consultant's opinion and advice provided the Company concerned will compensate him for this service in the same manner as the Group Plan Carrier would do if the member was thus insured.

All previous resolutions heretofore adopted, pertinent to malpractice claims and defense, are hereby rescinded.

Under date of February 9th, Louis A Van Kleeck, Harold L Barnes, George W Kosmak and Walter Lester Carr were appointed a Special Committee to consider the question of State Control of Certified Milk

James N Vander Veer was appointed Chair man Hyzer W Jones and Albert G Swift members of a Special Committee to confer with Commissioner Parran in regard to the Problem of Emergency Unemployment Relief in New York State

Daniel S Dougherty and Arthur W Booth were appointed a Committee on Transportation to the American Medical Association

A resolution presented by the Medical Society of the County of New York regarding the rendering of Joint Bills was not approved, as it was not deemed advisable for the Executive Committee to assume such a responsibility, as the resolution was considered to be in conflict with the Fellowship Pledge of the American College of Surgeons which provides that the practitioner obtain his compensation directly from the patient

The following resolutions were passed

That Dr Rypins, Sceretary of the State Board of Medical Examiners be written that the State Society is now ready to carry out the resolution of the House of Delegates, and asks that action be taken immediately against the Life Extension Institute

That the House of Delegates be memorialized concerning the continuation of the Committee To Prepare a History of Medicine in the State of New York and the Committee to Consult with the Saratoga Springs Commission in its Effort to Develop the Mineral Resources of Saratoga Springs

THE JOURNAL

The New York STATE JOURNAL OF MEDICINE for the year 1932 has continued its established policy of being the official organ of the Medical Society of the State of New York and of its com ponent units-the eight District Branches and the sixty County Medical Societies It covers the field of the practice of the individual physician, and also the field of activities of the Medical So It has maintained a proper balance of space devoted to these two fields and to commercial advertising, so that approximately one third of the Journal consists of scientific articles relat ing to the individual practice of medicine, one third to the activities of the medical societies, and one third to advertising. This allotment of space has not been the result of deliberate planning, but it has come about because the available material comes to the editorial office in surprisingly regu hr flow and uniformity of range. This division of space by pages during the last three years is shown in the following table

	1930	1931	1932
Seientific	537	573	576
Editorial	74	73	64
Medical Progress	96	96	96
Legal	62	70	66
News	220	272	270
Our Neighbors	137	153	129
Daily Press	48	48	44
Book Reviews	46	44	46
Advertising	615	633	565
	1835	1962	1856

The choice of articles in the scientific department of the Journal has been made from the point of view of the general practitioner in accordance with the opinion frequently expressed by outstanding medical leaders, such as Dr Frank Billings, that 'Tamily doctors should be able to give the best scientific service to ninety-five per cent of all sick persons" Most papers read before the several scientific sections of the State Society are addressed to general practitioners, for what is the advanced practice of specialists to day becomes the ordinary practice of family doc Many authors of the State papers tors tomorrow in the specialties ask the privilege of editing them so as to adapt the articles to general practitioners, and the other authors have edited the papers on being asked to do so The peculiar function of the scientific department of the Journal is to take up what the Commission on Medical Education calls the "Lag" between the production of knowledge by research workers and its distribution to general practitioners of medicine

The amount of space devoted to the several divisions of medical practice has been well bal anced as is shown in the following table

Analysis of the Subjects of Scientific Articles in the Journal for 1932

THE COME IN THE	Jookin	T JOR I	752
Nu	Number of		
Subject A	rticles	Pages	of Space
Medicine	50	215	37
Surgery	24	93	16
Genito-Urinary	13	45	8
Gynecology and Obstetrics	11	39	7
Pediatrics	13	49	8
Mental	2	6	
Laboratory	2	6	
Skin	8	40	7
Eye Ear Nose and Throat	7	24	4
Economics & Administrative	19	75	13

An analysis of this table shows that articles on Internal Medicine have filled about one third of the scientific department of the Journal, articles on surgery, about another third, while articles

on the other specialties and on economics, and medical administration fill the other third.

The subjects of Medical Economics and Medical Administration are set forth in a concrete way in the two departments of News Notes and Our Neighbors. The articles in these departments record the actual practice of the activities of Medical Societies in distinction from an exposition of the science, philosophy, and history of those activities.

The size and importance of the news depart-

ments of the Journal have kept pace with the phenomenal growth of the interest which physicians have taken in the practice of public medicine. The time is rapidly approaching when this branch of medical activity will be practiced to such an extent that a special department of the Journal may be assigned to it.

Respectfully Submitted.

Daniel S. Dougherty, Secretary.
February 15, 1933.

REPORT OF THE COMMITTEE ON MEDICAL RESEARCH

To the House of Delegates: Gentlemen:

In behalf of your Committee on Medical Research I have the honor to present the following report:

For six months prior to the current session of the Legislature sporadic newspaper publicity made it apparent that a new society headed by Miss Mabel Orgelman and called the New York Committee Against Vivisection on Dogs had entered the field of objectors to scientific experimentation on animals. This in addition to the older New York Antivivisection Society of which Mrs. Diana Belais has remained President.

Soon after the opening of the Legislature. Assemblyman Vaughan introduced his perennial bill to exempt the dog from all experimentation, which measure is sponsored by the N. Y. Antivivisection Society. Some day later, Assemblyman Bernhardt introduced a new bill, with exactly the same object and sponsored by the N. Y. Committee Against Vivisection on Dogs. Both of these measures are now in the hands of the Assembly Committee on Codes and a hearing on them is scheduled for March 14 next. Assemblyman Bernhardt also introduced a resolution for the appointment of a Commission to investigate all laboratories in the State and report to the

Legislature on or before February 1, 1934, with an appropriation of \$2,500. This resolution is it the hands of the Assembly Committee on Ways and Means.

Your Committee has made the usual endeavor to inform the legislators and the public of the danger to public health and medical progress the enactment of the proposed laws would entail. To aid in this purpose, two pamphlets were distrib-The one, a reprint of the Cannon and Drinker article, "The Dog's Gift to the Relief of Suffering," which details the latest achievements in medicine which are the result of experiments on dogs. The other, "Why Animal Experimentation is necessary for the General Welfare," includes a collection of letters from outstanding citizens of the State, among them the Presidents of the various universities, uniformly condemning any interference with properly conducted animal experimentation.

Your Committee will be suitably represented at the hearing on the measures in question and hopes to succeed in convincing the legislators that these proposed laws are contrary to the best interests of the public.

Respectfully submitted,
FREDERIC E. SONDERN, Chairman.
February 15, 1933.

REPORT OF THE COMMITTEE ON ARRANGEMENTS

To the House of Delegates: Gentlemen:

Your Committee on Arrangements announces the following arrangements for the Meeting of the Medical Society of the State of New York, to be held on Monday, Tuesday and Wednesday, April, third, fourth and fifth, at the Waldorf-Astoria Hotel, New York City.

All arrangements are completed for the meeting of the House of Delegates. Fine exhibits, both technical and scientific, will be given.

The Delegates Dinner, which will be held on the evening of the meeting of the House of Delegates, will be a little unusual this year insomuch as the President has arranged for two guest speakers to present two issues of vital importance to the profession. One is "Compulsory Health Insurance and Panel System" by Dr. Emil Koffler; and the second is "The Participation of the Physician in Public Health Work" by Dr. Henry Vaughan of Detroit. There will be present at the dinner Dr. George C. McCleary, of London, who is Deputy Senior Commissioner of Health.

On Tuesday, the Annual Banquet-Meeting of the Medical Society of the State of New York will be held, under the presidency of Dr. Chas. Gordon Heyd. At this dinner, a few men of national reputation and authority will speak on the future of medicine and the responsibility of the community to the physician. The details of the program wil be published in the STATE JOUR-

NAL at the proper time.

There is an additional feature which we have arranged for this year; namely, dancing on the roof garden of the Waldorf-Astoria after the dinner speeches, which are going to be definitely fixed for certain hours. It is hoped that the members and their wives will utilize their dinner tickets to come to this social gathering.

Arrangements are completed for the Section Meetings and for two General Meetings in the Grand Ballroom on Tuesday and Wednesday afternoons. On Wednesday evening, there is to be an Open Forum Meeting, to which the public will be admitted on presentation of tickets. Very short addresses, on questions the public should know, are to be given by men of national reputation and authority. All in all, we look forward to

an enjoyable and instructive meeting. All who ean should arrange to be present.

The Committee on Arrangements desires the profession to know that the tickets for the dinner are expected to be in demand; and seating lists will close the Saturday evening preceding the meeting. There will, of course, be unassigned seats in the back of the room. Seats will be reserved in the order in which applications are received. It is respectfully suggested that all who read this send for their reservations by mail to The Medical Society of the State of New York, 2 East 103rd Street, New York City. The tickets for both the dinner and the dance are five dollars.

Respectfully submitted
SAMUEL J. KOPETZKY, M.D.,
Chairman,

February 15, 1933.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates:

The Board of Trustees met regularly at two month intervals during the past year. Realizing the responsibility of conserving resources and maintaining a balanced budget, all proposals for the expenditure of funds of the Society were carefully weighed before given approval. It is gratifying to report that the activities of the Society have been maintained within the limits of the budget, and that the financial condition of the Society remains satisfactory.

Reference was made last year to the depreciation in market value of some of the investments. We are pleased to report that since then there has been a recovery amounting to \$7,838.75. During the past fiscal year, ten one-thousand U. S. Treasury bonds were purchased and placed in the investment fund which now totals \$104,401.50 (market value as of December 31, 1932). It is recommended to continue the policy of annually

augmenting this investment fund.

The Trustees again urge upon the Delegates and all those proposing activities which involve the expenditure of funds, to carefully consider the ultimate cost to the Society. Momentous problems, possibly epochal in character, now confront the profession. These must be met with intelligence and vigor, and unquestionably will require substantial sums to preserve our present professional ideals and status. We must put our house in order and be amply prepared. For this

reason, if for no other, the Trustees recommend that the present annual dues be maintained, and that all reasonable efforts be directed towards economy.

An analysis of the disbursements of a member's annual dues shows that less than eighty cents go to the investment fund. Personal benefits of Legal Defence, the Journal, and the Directory consume a considerable portion, while the remainder defrays executive office expenses and the cost of the various Society activities, all of which originate in the House of Delegates and the Excutive Committee. The members should also consider that a vast amount of time and conscientious work are donated annually by the officers and those composing the various committees, the benefits of which are shared by the entire membership.

It is very evident that a reduction in dues will necessarily demand curtailment of Society activities, and that no discussion of change of dues is logical without considering this fact.

The Board desires to express its appreciation of the Treasurer, Dr. Sondern, who attended all our meetings and whose valuable advice has been of inestimable aid, particularly on investment matters.

ARTHUR W. BOOTH, M.D., Chairman.

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

To the House of Delegates:

Gentlemen:

Your Public Relations Committee, now consisting of seven members instead of five as heretofore, is as follows:—William H. Ross, M.D., Secretary, Brentwood; George M. Fisher, M.D., Utica; Oliver W. H. Mitchell, M.D., Syracuse; Augustus J. Hambrook, M.D., Troy; William D. Johnson, M.D., Batavia; Thomas H. Cunningham, M.D., Glens Falls, and James E. Sadlier, M.D., Chairman, Poughkeepsie.

This committee has continued to form contacts with the various governmental and lay organizations working in the health field. These conferences have been most satisfactory in establishing harmonious and cooperative action, demonstrating the wisdom of the society in developing a committee such as this, to whom the various governmental departments, especially the State Department of Health, The State Department of Education as well as the lay health organizations, can appeal in order to obtain the viewpoint of the medical profession. It is doubtful if there has ever been quite as satisfactory a relationship between the medical profession and these various groups as exists at the present time. Your Committee considers that this alone justifies its existence and the necessary expenditure of money.

In order to form a closer relationship with the chairmen of the Public Relations Committees of our sixty county medical societies, this committee divided the state into ten regional districts and is meeting each month in one of these districts. During the forenoon the committee meets in executive session and transacts such state-wide business as is required. The meeting is continued during the afternoon as a regional conference with the chairmen of the Public Relations Committees of the counties in that section of the state. Eight regular and many special meetings have been held so far this year.

We are impressed with the importance of this arrangement which enables us to determine and evaluate just how each county society is handling its medical public relations. At the same time it gives your committee a chance to advise with and suggest to each county chairman plans of procedure.

In addition to the chairmen of the Public Relations Committees of the County Medical Societies we also invite to these conferences a few of the key men or leaders of the medical profession in that particular district. Hence we have a round table conference which cannot help but be valuable in the establishment of more harmonious cooperation between the medical profession and the various health agencies.

In our letter of invitation to the county chairmen we endeavor to outline the particular fea-

tures of the conference which we hope they will discuss, as for example:—

1. What has your committee done to help establish a working relationship with the governmental and lay health organizations?

2. Are you cooperating at the present time in

any important piece of health work?

3. What educational health activities are occurring in your county?

4. What are your physicians doing to secure satisfactory support from the Board of Supervisors with reference to Public Health activities?

5. Is the profession assuming a leadership in

your county in all health programs?

Your committee is receiving most enthusiastic support from the chairmen of the County Medical Societies Public Relations Committees.

Furthermore, we are impressed by the fact that the work done in the past six years by your committee has developed a large amount of real earnest work in the county units, hence we feel encouraged by the results of our efforts.

The following bulletin issued to our county chairmen, presidents and secretaries of the county societies and others, outlines the "Aims & Pur-

poses" of this committee.

"The Public Relations Committee of the Medical Society of the State of New York herewith submits a statement of the Aims and Objectives which it will strive to achieve during the year.

"This committee is undertaking to translate into County Medical Society activity the knowledge that it has gained of the problems of medicine in the last six years. In the beginning the work of the committee was largely fact finding. As information has spread the need for constructive activity in the problems of medicine has increased. The aim of the Public Relations Committee is to assist the physicians of the County Medical Societies in providing the public with the best medical service possible. This is the prime objective. Achievement, however, will depend upon a number of factors; among them three stand out as most important.

"1. By creating harmony among all medical and public health workers. There is an interrelation between all agencies seeking improvement in health and medical services. If the Public Relations Committee can help to develop a common program between all agencies in health work, it will have accomplished its primary purpose.

"2. By aiding the public to recognize good medical service. The rapid advancement in medical knowledge and medical practice makes it necessary to keep the public correctly informed so that it may reap the full benefit of the advancement in medicine. The Public Relations Committees of the County Societies should feel

a responsibility to the people of their counties for a correct knowledge of what is good medical practice and what the citizen should do to protect his health. Some of the county societies are already engaged in doing this by giving radio talks and addresses at public mass meetings or in places of industry. Some are making use of newspapers in describing good medical procedure. One of the serious conditions which must be thought of in publicity is the danger of encouraging self-diagnosis and self-treatment. The Public Relations Committee in entering this field is stressing particularly the importance of the advice and counsel of the family physician.

"3. By stimulating physicians to become active members of public movements in health and welfare. Physicians should take a leading part in all lealth activities just as the Bar has done in political or historical activities. Physicians should have a similar feeling regarding their position in health and welfare activities and they should feel that it is their prerogative to join with official bodies in developing health and welfare programs.

"The technique of putting these suggestions into operation must be worked out by each County Medical Society Committee. It is not expected that a program can be devised that will fit each county. Local conditions must be considered by the Public Relations Committee of each county

medical society.

"A basic need is harmony and cooperation between the physicians represented by County Medical Societies and official and unofficial health organizations. Physicians should take a civic interest in public health and medical service problems. Wherever public health can be directed by local physicians, it should be done.

"It is increasingly apparent to this committee that the problems of medical public relations must be solved in the County Medicol Society and that the function of the State Public Relations Committee is to stimulate interest in the solution of medical problems by the County Medical Society and to take leadership in the solution of problems that are state-wide. For example, in some departments of the state service full time men are permitted to engage in private practice of medicine. The Public Relations Committee is now engaged in an effort to correct this.

gaged in an effort to correct this.

"A primary problem in County Society administration is to inform and arouse the interest of its members in their own behalf and in behalf of public welfare, so that physicians may become leaders in the solution of medical problems. In the present period of general unrest and the many influences at work toward the solutions of medical problems, the profession of medicine should

give intelligent leadership.

"There are many opportunities for the profession to improve public welfare and at the same time their own economic status, by helping to

meet present-day problems. To this end the Public Relations Committee is holding this year regional conferences for the purpose of hearing a discussion of the problems of medicine from each County Society of the State and for receiving their suggestions of how these problems can be met and then coordinating them in a policy of public relations which will meet the situation between the profession, unofficial and official health agencies, and satisfactorily solve the conomic relation of the profession to the administration of these services of whatever kind they may be."

Your committee, in conjunction with the Committee on Public Health and Medical Education and the Division of School Inspection of the State Department of Education, is stimulating greater interest in medical examination of school children. This work is in some localities most efficiently performed, but we regret that in many localities it does not meet adequate standards, Furthermore, it is to be deplored that more of this work is not performed by the family physician. At the present time throughout the upstate section, but fifteen per cent is so handled. In view of these facts the following letter was formulated, received the approval of your Executive Committee and was mailed to school superintendents, medical examiners, members of Public Relations Committees and others throughout the state who are or should be interested in this important subject.

Subject: School Medical Inspections.

"The Medical Society of the State of New York, through its Committees on Public Relations and Public Health and Medical Education, has been cooperating with the Bureau of School Medical Inspection of the Department of Education, with the object in view of making these school examinations a serious and painstaking investigation of the physical condition of the child.

"It is the wish of the Medical Society of the State of New York and of the Department of Education that these school examinations shall be made by the family physician when possible, and in this way not only obtain for the child the result of such examination by the home doctor but, likewise, impress upon the mind of the youth of this country the necessity for a careful evaluation of their physical condition, with the hope that in later years, when they are men and women, they will still carry on and have such annual physical examinations.

"At the present time altogether too few physical examinations of school children are made by the family physician. We hope that in the future this will be different.

"In the Borough of Brooklyn and the Borough of Queens, approximately fifty per cent of such examinations are made by the family physician, and this year the Bronx County Society reported

that above ninety per cent of the high school children were examined either by the family physician or by physicians appointed by the County Medical Society to do the work. Why can we not have the same conditions in the rest of the state?

"It may not always be possible or practicable for the school children to be examined by the family physician, and in many such instances regularly employed physicians are doing the work thoroughly and conscientiously, with very satisfactory cooperation from school officials. It is not intended that this communication should interfere in those places, but rather that it should help support school officials and physicians so employed where conditions are less favorable, to achieve more efficient and satisfactory examinations

"It is to be hoped that proper and adequate facilities will be furnished and that there will exist between the medical examiner and the school authorities a mutual feeling of harmony and cooperation in the handling of this important piece of work, which may mean so much to the future health and happiness of the child.

"To the school medical inspectors throughout the state we beseech your very earnest coopera-

tion."

The Executive Committee has from time to time, referred certain matters to this committee for investigation and adjustment, all of which requests have been complied with and reported back to the Executive Committee.

The following are some of the subjects which have been considered and investigated by this

committee during the past year:

A study and ultimate decision with reference to the project about to be undertaken for the control of Venereal Disease by the State Charities Aid Association through its State Committee on Tuberculosis and Public Health.

A thorough investigation is being conducted with reference to the Department of Correction allowing full time physicians to engage in private practice in their particular locality to the detriment of local medical men. This subject is one of vital importance and through lack of correction has become a state-wide evil. Your committee would appreciate and desires the approval of the House of Delegates to continue this investigation and endeavor to correct the abuse of full time physicians, paid by the State, entering the private practice of medicine, thereby interfering with the normal practice of medicine by general prac-Naturally, this should not interfere with such men being used as consultants at the request of local medical men providing such consultations do not conflict with their duties to the

Conferences with the Medical Inspection Bureau of the State Education Department with reference to preschool and school examinations. Co-

operating with the Medical Inspection Bureau of the State Department of Health with relation to anti-tuberculosis work in the schools of the state. Conferences with reference to state aided county hospitals. Conference with a committee of the Nassau County Medical Society with reference to the care of the crippled children of that county. Report of the Ratio of Hospitals to Population. This latter subject was suggested by a member from Buffalo and referred to this committee but was not made as it centered around the general municipal law and should be cared for by the legal department.

The Chairman of this committee or the Executive Officer, Dr. Lawrence, representing the chairman, has attended the meetings of the Coordinating Committee of the five counties comprising the Metropolitan District. By so doing much valuable information has been obtained as to Medical Relations as they exist in the greater city and their influence over the state. Your chairman desires to express his appreciation to the members of the Coordinating Committee for the courtesy of being invited to participate in their conferences.

Your committee has issued bulletins frequently to the county committees and other members interested in our work. These bulletins serve the purpose of stimulating the county committees and also supplying them with necessary information regarding the aims and activities of the State Committee. We believe that such bulletins are a real factor in helping to produce a most agreeable relationship between this committee and its county units, resulting in a decided betterment in medical relations throughout the state.

Again this year, we are pleased to report that the Deans of the nine Medical Schools of the state have each signified their desire to have a member of this committee deliver a lecture to the third and fourth year students upon the subject "Organized Medicine and Medical Laws."

The committee selected Dr. William H. Ross, a past president of this society, to deliver this course of lectures. The cordial response of the medical schools of the state to this innovation upon the part of organized medicine is appreciated by the committee.

This should form a connecting link between the future physician and the organized medical profession and instruct him with reference to civic medicine and the laws affecting the practice of medicine.

The above represents a few of the many subjects that have been considered.

Throughout the year there has been a very cooperative relationship between this committee and the Committee on Public Health and Medical Education through its chairman, Dr. Thomas P. Farmer, who has attemded our meetings and conferences and given unstintingly of his time and valuable advice. The work of these two commit-

tees interlocks to a very great extent.

We desire to acknowledge our indebtedness to our Executive Officer, Dr. Joseph S. Lawrence, for the faithful and invaluable service he has rendered this committee throughout the year. It would be quite impossible to carry on this work and develop the necessary contacts without his advice and assistance.

The committee wishes to express its appreciation to the Editors of the New York State Journal or Medicine for having given a large amount of space to reporting its activities, there-

by enabling it to develop a correct amount of publicity and bring before the medical profession the result of its work,

Your committee is definitely impressed with the fact that the organized medical profession in the counties of the state is taking a deeper and broader view of the civic responsibilities of medicine. In many counties it has extended to the point where medical leadership is definitely in evidence in all that pertains to health work.

Respectfully submitted,
JAMES E. SADLIER, M.D., Chairman.

February 15, 1933.

REPORT OF THE COMMITTEE ON SCIENTIFIC WORK

To the House of Delegates: Gentlemen:

Your Committee on Scientific Work has been active during the past year. Each Section Chairman has endeavored to develop an instructive program and we are sure you will be pleased with the excellence and wide range of topics presented for the advancement of medical knowledge.

Section meetings will be lioused in comfortable, attractive, well-ventilated quarters. These arrangements have been made possible by the cooperation of the Committee on Arrangements and the management of the Waldorf-Astoria. Particular attention has been given to the requirements of each Section and we trust that the members will find the rooms not only comfortable but accessible. The final program will give explicit directions for reaching each Section.

The opening General Session, Tucsday afternoon, will be given over to a symposium on, "Dental Conditions as They Affect General Health." This innovation was arranged by Dr. Theodore Blum and Dr. Peter Irving, who were able to induce extremely well qualified men to open the Session with carefully selected topics. This joint gathering will add another link to our chain of intimate associations and bring medicine and dentistry into closer harmony.

The other General Session, Wednesday afternoon, will be devoted to the consideration of "Some Disorders of Liver Function." The essayists have had unusual experience and their contributions will be most instructive.

We are happy to announce that the President of the American Medical Association, Dr. Edward H. Cary of Dallas, Texas, will be with us and also that Dr. Olin West, Secretary of the American Medical Association, will favor us with his counsel and presence.

The Committee feels confident that the members will profit by attending all of the Sessions which have been so carefully prepared for their edification.

The Scientific Exhibit, instituted last year, will occupy much more space and under the efficient direction of Dr. Frederic E. Sondern will be well shown. The Committee on Arrangements has planned so that those who register will be routed through the Exhibit and all will be amply repaid for the time spent in the display room where the practitioner will find many excellent demonstrations.

The program for Monday, April 3rd, the Clinical Day, is under the direct supervision of Dr. Irving and his local assistants. A complete list of hospitals, operations, ward rounds and other attractive features will be available when you register. It is our earnest hope that a large crowd will come to New York City on Monday to receive the full benefit of these clinics.

The printed program will follow the lines inaugurated last year and will include not only the author's title but also a brief abstract of the material that he is to present.

The Chairman takes this opportunity to express his appreciation of the work of the Chairmen of the individual Sections, the tireless energy of Dr. Sondern, the whole-hearted support of Dr. Irving and the skillful help of Dr. Heyd, Dr. Dougherty and Dr. Kopetzky.

Respectfully submitted,
ARTHUR J. BEDELL, Chairman.
February 15, 1933.

REPORT OF THE COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

To the House of Delegates:

Gentlemen:

Your Committee on Public Health and Medical Education begs leave to submit the following report for the current year.

Owing to the early date of the annual meeting and the necessity of submitting this report in time for publication before the meeting, it is impossible to cover the activities of the Committee for the entire year, or to give details regarding activities. With these exceptions the present report follows the general form of the previous reports from this Committee.

GRADUATE EDUCATION

Table number one is a report of the graduate courses sponsored by the State Society for county medical societies under the direction of this Committee for the current year. It is understood, of course, that there may be some change of plans in this program subsequent to the time of this report. The title after each county refers to the subject of the course, and the figure refers to the number of lectures given in that course.

County	Subject	Number of Lectures
Chemung	Internal Medicine	0) 250011163
Cortland	Total Medicine	•••••• б
Herkimer	Internal Medicine	6
Rockland	Traumatic Surgery	• • • • • • • • • • • • • • • 4
St. Lawrence	Cumanic Surgery .	· · · · · · · · · · · · · · · · · · ·

Table No. 1.—Courses of instruction given through county medical societies.

Statistics:—The committee has continued to keep detailed records of the courses which it has sponsored. However, as only a small part of this year's activities have been completed, a detailed comparative summary of the work for the different years would not be worthwhile. Such a summary, however, will be submitted after the completion of all courses. Despite the absence of these figures the Committee has definite facts to report which are indicative of the trend of its work and suggestive of its value.

This year represents the sixth year during which this work has been sponsored entirely by the State Society; and during this time, assuming that the present year's program will be completed as now arranged, there will have been given 116 courses comprising 622 lectures. These eourses were actually given in 37 different county societies; but inasmuch as 10 other county medical societies have on one or more occasions joined in

participating with a neighboring county in some of these courses, the work has actually reached 47 different counties, representing approximately 70% of the membership of the State Society.

It should be remembered that the list of county societies where graduate courses have not been given includes several of the large counties where graduate education has been locally sponsored, as well as other county societies which had graduate lectures on Obstetrics and Pediatrics or both, when that work was given under the combined efforts of the State Department of Health and the State Medical Society. Apparently only Allegany County has not been reached by any form of grad-

uate education during these eight years.

Appraisements:—An effort should be made to arrange for some form of graduate education on the part of counties which have not participated in this work since the State Society has taken over its entire control. Reasons for the absence of this work in these counties, after the Committee has made every effort to provide courses for all county societies, are the lack of acquaintance with the work, lack of initiative of the officers of the county society, or lack of leadership in the county society. Six county societies in which courses were given last year have not arranged for courses this year, though it is possible that four of these may still arrange such courses, and it is very probable that two of these will do so. The remaining two counties consist of a very large county where the work offered by the State Society supplemented graduate work locally sponsored, and a small county in which it would be unwise to repeat a course every year.

Two counties on this year's list did not have a course last year, and again represent a large county where the State Society is supplementing local graduate work and another small county society in which a course each year would be superfluous. Fourteen county societies which have arranged courses for this year had courses last year and all except two of these had courses the year before. Twenty-four county societies of the 37 different counties, in which courses have actually been given, have had more than one course, while 20 have had three or more courses. Four societies have had a course each year for the entire six years comprising the time the State Society has sponsored this work. Five counties have had a course for five years, and in two of these the courses have been held in consecutive years. Eight societies have had a course each year for the past 4 consecutive years. counties represent all sections of the State geographically as well as varying conditions consisting of both large and small counties, and counties largely rural and wholly urban in population.

These facts demonstrate that the program of

the State Society for graduate education has been carried to a large proportion of its membership in The tendency for widely distributed sections county societies to repeat this work so frequently would seem to indicate that the work has been fairly satisfactory to many societies where it is looked upon as a regular yearly feature of the so ciety's program of ictivities. Each year this is further demonstrated by letters of appreciation received by the committee from the various county societies. During the present year the committee has received a set of resolutions adopted by one county society, personally signed by its different members, expressing the gratitude of that society for the efforts of the committee Another society in which a course has been completed this year is now planning for a course to be given next fall One county society has sent to the committee an analysis of the attendance of its members at the course presented in that county

These expressions from county societies are not only help ful to the State Society's Committee but have been a compensation for its efforts and a stimulus to make the work of greater value and greater interest

The committee has continued its general plan of graduate education as carried on for the past The work has been given in five or six weekly lecture courses usually at sessions other than those of the regular county society meetings Nearby counties have continued to agree on having the same course so as to save expense and facilitate arrangements The courses have dealt with practical subjects, the mijority of them having been in the field of internal medi-The committee has endeavored to make its plans as elastic as possible in order to meet local conditions without upsetting the purposes of the work In arranging the courses the chairman lins taken advantage of attending the sectional meetings of the Public Relations Committee in order to have personal conferences with representatives of the county societies The curtailment of railroad service in certain sections of the state has added some difficulty in the arrangement of courses but on the other hand the railroads have shown a splendid spirit of cooperation in agreeing to stop some of their fast trains at different places to facilitate the program of the committee

One new course has been added to the list of courses which the committee is prepared to offer to county societies. This course was outlined by Dr A F R Andresen of the Long Island College Hospital and is a course in Internal Medicine dealing with gastro enterological topics. The committee has initiated an innovation with one of its courses (Dr Greene's course on Internal Medicine) in supplying mimeographed outlines of each lecture to all those present. These out lines have proven to be most valuable in that they have added interest and provided permanent notes.

of the lectures They have been very much apprecated by physicians who have been compelled, for some valid reason, to miss one lecture in the course

Future Plans -The Committee is prepared to offer an extension of its program under two new plans The first plan is possible through the offer of the Administrative Board of Post-Graduate Studies in Medicine of Columbia University to present to a group of at least 20 physicians a course in New York City of one week's duration Outlines for three different courses have been pre-These outlines differ considerably should appeal to almost any man in general prac tice, another to a man in general practice who is doing obstetrics and pediatrics, and, the third to a physician who is somewhat interested in public It is expected that Columbia University will charge a registration fee of \$1000 for these This committee is endeavoring at this time to iscertain if enough physicians would be interested in registering for these courses and to learn when such courses should be presented in order to be as convenient as possible for those interested in taking the courses. The committee hopes that similar courses will be planned in other medical centers in the state and particularly urges that in arranging such courses the local county medical society actively participate in this work

The second plan comes direct from the committee and is a change from the weekly lecture course to a clinical conference plan The scheme of a clinical conference is to have physicians in an area bring to the meeting some half dozen cases which present concrete problems either in diagnosis or tre itment These cases should be brought to the center where the meeting is to be held early in the day, thus allowing the guest chief of the clinic an opportunity to study these cases Then, at the time of the meeting the patient's physician pre sents the case and gives his point of view patient is shown and the case is opened for general discussion, and finally the guest chief summarizes his own findings, expresses his own opin ion and makes his recommendations It would be desirable, if possible, that not only an internist but a surgeon as well constitute a team would encourage an enlargement in the type of case that could be brought in and would also in crease the general interest by giving different points of view. It is recommended that the work in graduate medical education be extended to in clude clinical conferences and that this plan be tried in some counties as an experiment in place of post-graduate lectures

Recognitions — Each year this committee receives requests for information from other organizations regarding the work of the Medical Society of the State of New York in graduate education. During the past year such information has been supplied to the Massachusette Medical So

ciety as well as to a local society in a city outside the state.

In the final report of the Commission on Medical Education reference is made to the work of this Society in providing its extension courses and in its conclusions dealing with post-graduate medical education the Commission lists these courses as one of the three major phases of post-graduate education. The Report states:

"A comprehensive program of post-graduate education can be conducted only through the cooperative endeavor of the medical associations, medical schools and hospitals. The most important and largest part of the program should be directed toward taking educational opportunities to the practicing physician in his own community or to centers to which he can go without leaving his practice."

It is comforting to know that our State Society has not lagged in providing a vital part of an adequate program of medical service for the public.

PUBLIC HEALTH ACTIVITIES

In the report of this committee under a different chairmanship submitted to the House of Delegates in 1926 the statement was made that, "In the continuous education of the practicing physician we see the greatest single contribution that organized medicine can make." Each day it is being generally realized that medical service is the most important activity in the field of public health and that continuous education of the physician is an essential for good medical service. It is also further accepted that such continuous education is the province of organized medicine, if not in whole, at least, in a large part. It is generally accepted that a state medical society's program dealing with public health must give major consideration to the subject of continuous education of the practicing physician.

While a large part of the committee's time and attention has been concerned with graduate education, nevertheless it has been active in other fields of public health. In this connection it is pleasing to report an evidence of increasing cooperation on the part of other organizations toward the medical profession.

Maternal Mortality Study:—In last year's report mention was made of the study of maternal deaths to be undertaken by the State Department of Health. This study is well under way but has not been completed. Some of the material obtained from the study has recently been sent to the committee for review. A sub-committee consisting of Doctors Kosmak, Foster and Farmer will take charge of the review of this material. A complete report will be made by the committee after all the material has been reviewed. It is expected that Doctor Kosmak will present a state-

ment regarding the progress of the study to the section on Obstetrics and Gynecology at the annual meeting. The committee has considered requesting the extension of this study to a period of three years. No decision on this point, however, can be made until some estimate of the value of the first year's study can be formed. Each county medical society has been requested to give its reaction to the study. The replies from the county societies so far heard from have been favorable, with the exception of two counties which opposed only that phase of the study which permitted a state physician instead of the family physician to obtain information from the family. The committee is in complete agreement with these county societies on this particular phase, and it is their understanding that the State Department of Health has subscribed to this plan.

Tuberculosis Reporting:—Reference also was made in last year's report to this subject. Two conferences between representatives of the State Department of Health and this committee have been held to consider means whereby the reporting of tuberculosis might be improved. What at first seemed to be a simple subject has turned out to be a complex problem. Because there seemed to be some uncertainty on the part of some physicians as to what cases should be reported, the first step was to agree on a definition of what constituted a reportable case. These conferences brought out that case reporting of tuberculosis is far from satisfactory and that methods previously used have been ineffectual, that the trend to the institutional and clinic management of the tuberculosis patient has proceeded to such great proportions as to possess the disadvantage of lessening the physicians' interest in this problem; and that there is some question as to whether undergraduate medical clinical instruction in tuberculosis is always adequate. As a means to improve these conditions an effort is to be made to increase the teaching of tuberculosis to medical students wherever it seems inadequate; to enlarge the program for post-graduate instruction on tuberculosis before county medical societies; to publish appropriate articles in the State Medical Journal pertaining to the whole problem; to bring back to the physician more medical supervision of the tuberculosis patient; and to formulate a practical simplified system for the reporting of this dis-

Cancer:—Under the direction of this committee 13 counties either have had or have arranged for a meeting during the year devoted to the consideration of cancer. Most of these talks have been of a practical nature emphasizing the physician's part in the management of such cases. Some of the lectures were provided through the up-State Committee of the American Society for the Control of Cancer with whom this committee has been actively cooperating. The arrangements

for all of these talks were made through this committee.

Medical Inspection of School Children:-As a result of discussion by the Committee on Public Relations of complaints regarding unsatisfactory school examinations in one county, this matter was referred to the Chairman of the Public Relations Committee and the Chairman of the Public Health Committee. At a conference between these two chairmen and a representative of the State Department of Education it was learned that there were about 8,000 rural schools in the state, employing about 20,000 teachers, and grouped into 208 districts, each district supervisor having from 25 to 75 schools in his district. Each of these rural school districts has a separate commisioner with rather broad powers of administration. The district supervisors apparently have little authority. It is apparent therefore that the system of organization of these schools adds to the difficulty of the problem of the medical examination of school children.

conditions in this type of work are incompetent examiners, politics, unsatisfactory places for making examinations, lack of contact between the parents of the child and the examiner, lack of cooperation on the part of the teacher. The only means by which these conditions can be improved would seem to be through the investigation by the county society of this problem within its own confines; by efforts to have these examinations made by the family physician in all eases possible; and by a request for better cooperation from both physicians and teachers. A letter urging such cooperation has been prepared and approved by the Committee on Public Relations and by the Committee on Public Health and Medical Education. The term "medical inspection of school children" as it now appears in the law, we believe, should be changed to the "medical examination of school children."

Other factors contributing to unsatisfactory

Periodic Health Examinations:—This subject was referred to this committee last year when the special committee for this purpose was abolished. The committee is impressed with the advance being made in periodic health examinations. Doctor Crampton, who has acted with the cominitice, informs the committee that two large business organizations have adopted the health examination, one as a requirement and the second as a strongly recommended optional procedure. The committee would therefore urge all county societies to furnish timely instruction to physicians for health examinations wherever that seems necessary. The question of certifying physicians who are willing to give such health examinations and have demonstrated satisfactory evidence of abilty to do so, is a matter which we believe should rest with the county societies.

MISCELLANEOUS SUBJECTS

Physical Therapy:—As a continuation of the educational phase of the work in physical therapy, single talks were given before the Ulster, Washington, Sullivan and Wyoming County Medical Societies, and a series of four lectures was given before the Queens County Medical Society.

In order to clarify some of the aspects of instruction and supervision in connection with the physio therapy clause of the Medical Practice Act, a conference was held with the Department of Education, and a satisfactory agreement as to the best viewpoint of the problem was reached.

Licensure of Graduates of Foreign Medical Schools:—It has been brought to the attention of the committee that residents of this country whose qualifications are not sufficient to admit them to medical schools in the United States are readily admitted to schools abroad and are granted degrees after the completion of that course, although in many cases they are refused the privilege to enter an examination for licensure in that country. This matter was discussed at an informal conference in Chicago on December 18th, attended by representatives of the medical profession, medical colleges and medical examiners, when the following recommendations were adopted:

1. That no American student matriculating in a European medical school subsequent to the academic year 1932-33 will be admitted to any state medical licensing examination or to the examination of the National Board of Medical Examiners who does not, before beginning such medical study secure from a State Board of Medical Examiners or other competent state authority, a certificate endorsed by the Association of American Medical Colleges or the Council on Medical Education and Hospitals of the American Medical Association, showing that he has met the premedical educational requirements prescribed by the aforementioned associations.

2. That no studens, either American or European, matriculating in a European medical school subsequent to the academic year 1932-33 will be admitted to any state medical licensing examination, or to the examination of the National Board of Medical Examiners, who does not present satisfactory evidence of pre-medical education equivalent to the requirements of the Association of American Medical Colleges, and the Council on Medical Education and Hospitals of the American Medical Association, and graduation from a European medical school after a medical course of at least four academic years, and either,

(a) Obtain a license to practice medicine in the country in which the medical school from which he is graduated is located, or

(b) Receive the degree of Bachelor or Doctor of Medicine after not less than one year's resident study in an American or Canadian medical school approved by the Federation of State Medical Boards of the United States, the Association of American Medical Colleges, and the Council on Medical Education and Hospitals of the American Medical Association.

Regulations of the Public Health Council:—Objections to some recent additions to the Sanitary Code have been brought to the attention of the committee. This has been criticism of the regulations relating to blood transfusions. After reviewing this matter the committee feels these regulations are burdensome, inadequate and impractical in many instances. The committee does not believe that the responsibility of giving blood transfusions can be shifted to some remote agency, technician, interne, hospital or employee. This responsibility is solely that of the physician. We therefore disapprove of Regulation 8 because its rules for guidance in examination of donors are not in accord with scientific fact and clinical The regulation therefore does not meet in a sound workable manner such public health problems as may be involved. We disapprove of the burdensome, unwarranted and unenforceable duties Regulation 8 imposes upon hospitals, and which serves no good purpose.

Your committee favors all reasonable public health regulation. The regulations, however, should be in accord with accepted methods of medical practice and procedure. Any direct or indirect regulation of medical practice or hospital management other than for matters of public health, or any tendency to stretch public health regulation to cover that which is not in the ordinary sense a public health problem is an invasion of the field of medical practice not contemplated

by the statutes.

The Detroit Health Plan:—The committee has given attention to the plan of medical participation in public health work as it is now being carried on in the city of Detroit. Although this same subject is being studied by the Committee on Medical Economics, we believe that its public health aspect should be evaluated by this committee before any definite pronouncement is made. There is no question but that this plan has many decided advantages. Naturally it presents a radical change from the accepted method of caring for community health problems. Whether such radical changes could be made in a large number of communities within a short period of time is The human factor is an important element in the success of this plan and its effectiveness must naturally depend upon the personal qualifications of the local health chief, and the activity of the county society. Your committee would recommend further study of this plan by both the Committee on Medical Economics and this committee.

Distribution of Cod Liver Oil by Relief Agencies:—It is well known that at the present time many families are dependent upon public relief for food and housing. As a dietary supplement it has been recommended that cod liver oil should be furnished to such families especially when there are children in those families. Because there had been some objection on the part of some physicians to the distribution of cod liver oil without a doctor's prescription this matter was considered by the committee and the following statement has been prepared by the committee:

The artificial character of many basic foods in modern society requires that supplementary elements be considered. This is particularly true in respect to growing organisms, infants and children, and it is generally held that cod liver oil contains elements which are essential supplementary foods for growing organisms. Suitable amounts of cod liver oil daily should be a part of every welfare, low cost or limited choice diet particularly for children and during the winter months.

All cases of malnutrition and depleted states, in which extra amounts of vitamin A and D might be indicated, should be referred to competent medical authority for examination and treatment. Such extra amounts of cod liver oil as might be useful for the treatment of such cases should not be given except as prescribed by a physician.

GENERAL

The committee has held only two meetings this year, but has been able to transact a large amount of business by correspondence between its members at other times. Several questions have been cared for in this manner which, of course, has resulted in a large saving of expense. Many of the subjects which the committee has considered during the past year have been handled by subcommittees which, after studying the problem thoroughly, have submitted their findings to the whole committee.

The committee has curtailed its expenses in every possible way without injuring its services, and expects to finish its year's activities well within its allotted appropriation, despite the fact that it has taken care of the activities of two special committees which were delegated to this committee after the special committees were abolished.

The committee has continued to serve county medical societies in advising them regarding health problems and programs for their meetings. It has secured speakers for their meetings, and on one occasion provided the program from its own members. The chairman and members of the committee have represented the committee at various district branch and county society meetings.

The committee wishes to acknowledge the excellent assistance which it has had during the past year from the president and all the officers of the state society. The splendid cooperation with the other standing committees has continued. The committee also acknowledges its appreciation of the services of the various lecturers and all others who have assisted in organizing the postgraduate programs. The chairman is deeply grateful to the members of the committee for their valuable and unselfish service as well as their continual interest in the various activities of the committee.

In order to expedite the work of the House of Delegates the recommendations contained in

this report are herewith summarized:

RECOMMENDATIONS

1. It is recommended that every county society be urged to earry on some form of graduate education at suitable intervals.

2. It is recommended that the plan of graduate education as now carried on by this committee be extended to include clinical conferences.

- 3. It is recommended that the State Society give approval to short resident courses to small groups in large medical centers and that the county society of the counties in which such centers are located be urged to take the initiative in organizing such courses.
- 4. It is recommended that the State Society give its approval to a request of the committee to extend the study of maternal deaths to three years, provided in the opinion of the committee the first year's study has been of value, but too short to make the Study sufficiently comprehensive.
- It is recommended that the committee be directed to continue its efforts to improve tuberculosis case reporting along the lines suggested in this report.
- 6. It is recommended that approval be given to the statement of the committee regarding the use of cod liver oil as a food, with especial reference to diet furnished by relief agencies.
- 7. It is recommended that county societies be asked to study the work in medical school examination in their respective counties with especial reference to rural schools and with particular emphasis on the need of having such examinations made as much as possible by the family physician.
- 8. It is recommended that the State Society approve the recommendations as contained in this report regarding the licensure of graduates of foreign medical schools.
- It is recommended that the State Society take some action urging the appointment of active physicians to the Public Health Council for reasons of efficiency and public welfare.

10. It is recommended that the Committee on Public Health and Medical Education be directed by the House of Delegates to study jointly with the Committee on Medical Economics the Detroit Health Plan of medical participation in public health work and report their findings to the Ilouse of Delegates.

ADDENDA

1. Definition of a Reportable Case of Tuberculosis: All cases of pulmonary tuberculosis which have clinical significance should be reported. Cases free from symptoms and having slight pathological changes indicative of a healed lesion in the lung, as noted by x-ray, and which the clinician is relatively certain are bacilli free, should not be reported.

All other forms of tuberculosis such as meningeal, gland, bone, joint, etc., should be reported.

Children, who in the absence of other signifieant clinical findings, show evidence of tubercullous infection by positive tuberculin reaction, or x-ray, should not be reported. These children, however, may be recorded locally in order to allow for proper epidemiological work, including the examination of all intimate contacts.

2. Regulation 8 of the Sanitary Code: "The superintendent in charge of every hospital shall keep a record of every blood transfusion performed in such hospital. Such records shall be open to inspection by the state commissioner of health or his authorized representative, and shall include the name of the physician or surgeon making the transfusion; the full name, age and address of the donor; a certificate from a physician registered under the laws of New York State showing that a satisfactory physical examination of the donor has been made within ten days immediately preceding the offering of the blood donation and that such blood donor is free from communicable disease; a record of laboratory tests, including a complement-fixation test for syphilis, made in connection with the physical examination to determine that the donor was free from communicable disease; the blood group to which the donor belongs according to the Landsteiner elassification with the source of this information; if the donor belongs to the group of so-called "universal donors", a record of tests of his blood showing that his serum does not contain dangerous agglutinative properties for the blood cells of persons belonging to other blood groups; the time and place where tests were made which showed that the blood of the donor and recipient were compatible; the quantity of blood given; the full name of the recipient; the date of the transfusion, and the condition of the donor and recipient during and after the transfusion; PROVIDED, that if due to an emergency any of the above requirements cannot be met prior to transfusion, the records shall show the

reason therefor. This amendment shall take effect January 1, 1933."

Objections of the Committee Regarding Regulation 8 of the Sanitary Code: So far as the transmission of communicable disease is concerned, medical experience, as evidenced by reports of cases, indicates that even in the presence of a positive Wassermann test, without active symptoms of the disease, the hazard of transmitting syphilis by blood transfusion is negligible. Malaria, however, can be easily transmitted in both the active and latent periods. On the other hand, syphilis in the acute stage, even in the earliest chancre stage, can be transmitted by transfusion even so early that the blood Wassermann is negative. It would, therefore, seem that the best protection for the recipient is a physical examination of the prospective donor at the time of the transfusion together with a careful questioning of the donor with explanation to him of the seriousness of the situation.

This brings in line another comment on the regulation as a matter of public health. Damage to the donor is an important item to be settled only by a careful physical examination by a physician. If the donor is suffering from serious disease although not transmittable, or is in the early stages of some minor acute disease, giving of blood might be damaging to him.

So far as blood groups and blood matching are concerned, most of the accidents have occurred from a misunderstanding of the groups, confusion in nomenclature, misinformation or improper technique in grouping. It is our opinion that the best and only true protective method is cross matching of donor with recipient at the time of transfusion. The supposed group of the donor might be useful as a presumption of eligibility but except in grave emergency cross matching should be done. The so-called "Universal donor" should be accepted with reserve except in grave emergency. At any rate the ordinary grouping does not take into consideration Landsteiner's groups M and N which are disturbing factors. All the inaccuracies of the agency technician, confusion in the nomenclature of groups, errors of memory and of record are checked off by cross matching at the time of transfusion.

The giving of a transfusion is the responsibility solely of the physician in charge. He cannot shift that responsibility to some remote agency, to a technician, interne, hospital or employee. The responsibility is definitely his as a matter of law.

The final selection of a donor can best be made at the time of the transfusion and on the spot. Donor agencies and their records, including Wassermann tests, become less and less important as the necessity for physical examination of the donor at the time he is to be used and careful history taking and cross matching are emphasized.

A predated Wassermann test, even one but a week old, is neither conclusive nor sufficiently protective.

The part the hospital should play in regulating transfusions is no different than for any other medical or surgical procedure, and the reasons for Regulation 8 so far as it applies to hospitals is therefore obscure. The hospital may have a closed staff, permit only certain physicians or allow all registered physicians in the community to make use of its facilities; but as a corporation it has little to say, and should have little to say, as to how cases shall be treated, operations performed, etc. Such regulation, if any, is a function of the Staff. It is customary for hospitals to keep a record of each case to which the attending physician must contribute a history, results of a physical examination and daily comments regarding the progress of the case. All operative procedures are to be described therein by him. Combined with these data are the nurse's bedside notes, the laboratory reports, etc., making a running record of the case. All the data called for by Regulation 8 should and usually does appear upon this ordinary hospital record. For the hospital to keep a separate registry for blood transfusions not only means extra expense and trouble to them, now very much overburdened by record keeping anyway, but seems to serve no good purpose. The fact that in true emergency, a matter which can be decided only by the physician, all requirements are waived the record to show the reason for waiving it, is no recommendation for the regulation. A waiver of any or all regulations when it is not practical to comply with them for reason of an emergency yet leaving it required that the circumstances must still be recorded by the hospital in a separate register, adds petty annoyance to an unreasonable burden. To see that in each and every case regardless of the circumstances a record be kept is beyond the power of hospitals to comply. It is far outside the realm of public health regulation. Were such matters within the scope of public health regulation, one should think of the innumerable rules and regulations which could spring up to regulate the practice of medicine in hospitals. Attempting to regulate medical practice by a burdensome system of record keeping in the hospitals is an awkward expedient.

We disapprove the Regulation 8 as not meeting the public health problems involved in a sound and workable manner. We thoroughly disapprove of the burdensome, unwarranted and unenforceable regulations it imposes upon hospitals to no good purpose or practical advantage.

Respectfully submitted,

THOMAS P. FARMER, M.D.,

Chairman.

February 15, 1933.

REPORT OF THE COMMITTEE ON ECONOMICS

To the House of Delegates Gentlemen

The Committee on Medical Economics respectfully submits the following record of its activities for the current year

- It will be noted throughout our Report that the Committee has become more convinced than ever that justice and the welfare of all the people are the most important considerations in any de-When we cision which we may recommend condemn injustice to the tax payer or approve of a measure which saves the tax-payer money, this is what we have in mind. Also, the welfare of the people depends to a larger extent than we usually realize upon the study, care and decisions of physicians The disposition of any matter in the easiest way because it is the easiest way is The unwillingtherefore unwise and inhumane ness to alter habits and ways traditionally fixed may ultimately react upon the profession ever is best for all the people is best for its as a profession This "best for all the people" should be the stimulus to our initiative and the objective of all of our actions resulting therefrom
- 2. In planning the work for the year it was the unanimous opinion that the Committee should concentrate on a few important pressing problems rather than attempt to carry forward to final action a multitude of considerations. In a general way the sequence of headings will follow the sequence in the Report of 1932. The shortening of the administrative year has reduced our desired accomplishment by at least 16%
- 3. Projects undertaken and completed as far as recommendation to the House of Delegates and (or) the Executive Committee are

Proposed amendment to the Workmen's Compensation Law by a new so-called "Medical Section"

Study and recommendations concerning the Social Welfare Law

Completion of our study of the Detroit Plan of Public Health Service

Economic implications of the Public Health Council as now organized

Proposed amendment to the medical section of the General Municipal Law

The re-referred matters concerning the regulation of firms and corporations dealing with bill collections or financing for sickness

Consideration of the National Health Plan The re-referred matters concerning "Physicians and the Courts"

The heretofore unapproved recommendations concerning compulsory arbitration of automobile accident claims

Proposed amendment to the Lien Law providing for a lien upon the verdict recovery, settlement or financial return to one injured in an acci-

dent allegedly through the negligence of some one else

4. Projects which have been undertaken with the idea of gathering facts and conducting study through the current year and which remain incomplete at this time are

Many of the features of the economics of hos pitalization

Cost analysis of medical practice

Studies in relation to the outlet field for medical knowledge

Commercialized and industrialized medicine in-

Survey of Doctors under contracts to industry Survey of free and pay clinics in the City of New York

The Bassett Memorial Hospital, at Coopers town Insurance Plan of the United Hospital Fund,

New York City

Baker Memorial Hospital, Boston

5. Projects postponed for future consideration of this Committee

The Cleveland Plan of Clinic Control

U S Travelers Hospitalization Corporation California Insurance Plan of practice among persons of moderate means under jurisdiction of County Medical Societies

ECONOMICS OF HOSPITALIZATION

6. Your Committee is following with close observation the development of new forms for the analysis of hospital expenses by the United Hospital Fund We report that a new text on "The Budgeting of Hospital Funds" will be on the press soon The stress and difficulties of the time are bringing proper emphasis on "cost analysis" in hospital care. We recommend that physicians connected with the various hospitals throughout the State make inquiry as to the methods of "budget" and of "expense analysis," and that duplicates of blank forms, if any, be mailed to the Secrctary of this Committee for study and compari-Necessity, born in the agony of depression, seems destined to rectify wasteful methods of previous years

COMMERCIALIZED AND INDUSTRIALIZED MEDICINE

7. In considering the subject of commercialized medicine, it is apparent that throughout the country there are hundreds of plans under way, most of which antedated the Committee on the Cost of Medical Care Prominent among them are the Los Angeles Plan, including the Loss Clime, the Baker Memorial, the Massachusetts General Hospital and the Imogene Bassett Memorial at Cooperstown, New York. These all have elements about them which are highly to be com-

mended and under proper administration doubtless would fulfill the objects for which they are designed.

- 8. It would seem that a combination of the Baker and Bassett Memorials might work out satisfactorily both to institutional management as well as to the members of the profession involved. On the other hand, the new Plan of the California State Medical Society seems to fit in with some of the principles expressed by the members of the minority group of the Committee on the Cost of Medical Care. Doubtless this will be put in force in the near future and out of that experience may grow a satisfactory solution.
- 9. With the very definite opposition to regulated group medical activity, there is, nevertheless, a strong sentiment in the profession for cooperative medical endeavor of such a type that initiative will not be destroyed and compensation diverted unfairly.
- 10. Medicine in Industry.—In continuing the questionnaire with reference to medical practice and associated interests we have concentrated on the members of the profession who are concerned in industrial medicine in New York State alone.
- The same general information holds as was expressed by members of the National Industrial Conference Board who furnished the material of the first portion of the study. (Annual Report, 1932.) There are practically none of the physicians under definite contract with the organizations by which they are employed, in fact the general consensus of opinion is that they are week to week or month to month employees. This is particularly true of those who are on a part time basis. On the other hand, it is quite evident that with the full time medical employees who are engaged by organizations having sickness benefit and pension plans, a contract is implied, whereby the medical employee just as any other employee is entitled to payments under the plan for sickness or for retirement at the expiration of specified age limit. In practically all the returns the men expressed themselves as being satisfied with their compensation and that it filled a very satisfactory phase in their budget. The opinion with reference to a full time industrial work was rather more pronounced than one would expect, in view of opinions to the contrary stated by various members of the profession who have been in industrial work for long periods of time.
- 12. The latest questionnaire was directed to 46 members of the New York State Society for Industrial Medicine. These were sent to the men whom it was thought would be most liable to respond and respond most satisfactorily. They were picked from a group of several hundred who constitute this organization. The result expected was to the effect that these men were well satisfied with this type of work and feel that it

- has a definite place in medicine. It might be well in the future to continue brief questionnaires of this sort, particularly with reference to details of preference and manner in which any opinion of the various members might be solved.
- It is desired to repeat the statement that industrial medicine as an entity does not exist, but that medicine in industry is exactly the same as good medicine elsewhere and does not demand any particular academic investigation beyond that which is necessary in the understanding of various processes, materials and activities involved in the manufacture of various products or in the rendering of various types of service. It is apparent that during the present economic crisis in many parts of the country the medical organization, while personnel activities have been limited, is carried on even at considerable financial effort on the part of management. In some parts of the country, where public medical service is limited or of a type inadequate or undesirable, industrial medical departments have stepped into the breach and rendered emergency service. This has sometimes called for critical comments by the profession at large, but has been justified on the basis that such service, if not provided from these sources, would either not be possible at all or would be relatively inadequate. Where medical endeavor in industry has been fitted to the demands of the particular industry and certain of its personnel obligations, it seems to have fulfilled a desirable service both to the employee, the industry and the profession at large. It is to be remembered that industry is the basis of economic prosperity; that industry in buying raw products or particular service must recognize the social status of the sources from which these may be obtained and in the processes of fabrication or in the delivering of service the features of economic justice must be maintained. If the excellence of a product or of an industrial personnel endeavor has a medical feature in its composition, then the industry producing the same must see to it that this production does not interfere with the lawful sources of financial compensation due the members of the profession at large.
- 14. It would seem that, under certain compensation requirements, industries were justified in carrying on their own first aid and continued treatment of accident cases provided they were financially in the position of purchasing adequate service at charges commensurate with those prevailing in the several social and economic levels. Furthermore, where industry maintains sickness benefit and pension plans, the costs of which are ultimately passed on to the consumer in the form of operating costs or even where such payments are made out of surplus, it is justifiable for the industry to maintain diagnostic facilities or to otherwise purchase them with the object in view of determining the nature of the diseased condi-

tions present. This is of value to employee, employer and physician.

WORKMEN'S COMPENSATION LAW

- 15. Arbitration meetings and adjusted settlements avoiding arbitration on the part of the carriers and some of the County Societies have been continued accomplishments of the past year. The work has been done by and through the Committee on Economics of the County Medical Societies. The earriers have sought to limit the number of arbitration centers to the fewest possible number. They would prefer to conduct all arbitrations in New York City. This experiment has proven the practicability of the arbitration of all contested bills for medical care.
- 16. The report of Governor Roosevelt's committee, appointed to review medical and hospital problems, was so generally disapproved by the House of Delegates in 1932 and there were so many complaints of abuses of and defects in the law, that we are cognizant of general agitation for changes in the Law. Numerous bills for amending the Law luve been introduced into the 1933 Legislature.
- 17. Governor Lehman has appointed a special committee of medical men to make suggestions as to changes in the Law. Your Economics Committee, fortified by executive opinion, has formulated a new Medical Section to be proposed for insertion in a suitable place in the Law. In this, the Committee has been ably assisted by the advice of our Counsel. It is the aim that this Medical Section shall deal with all matters which involve medical services directly or indirectly. If this proposed Section is earefully considered and ratified as amended and modified by the House of Delegates it may prove to be of considerable value to Governor Lehman's Medical Committee.
- 18. Recommendations.—The following is a new Medical Section recommended for Inclusion Within the Law.

SECTION 13A. MEDICAL SERVICES.

Subd. 1. DEFINITION OF MEDICAL CARE. Medical care under this Act consists of the undertaking, by any means or method, to diagnose, treat, operate or prescribe for any human injury, disease, pain, deformity or physical condition arising out of industry and compensable under the provision of this, the Workmen's Compensation Law, by an eligible person.

Subd. 2. Those Eligible to Render Medical Care:

a. A person licensed and registered to practice medicine under Article 48, Section 1251 of the Medical Law of the State of New York; provided

b. Such physician shall register with his County Medical Society, and the Commissioner of Labor, his desire to participate in medical care under this Act.

to participate in medical care under this Act.
c. Regulations for registration provided for in paragraph b shall be established by the Commissioner of Labor with the concurrence of the Incorporated Medical Society of the State of New York, representing the medical profession of the State of New York.

d. Emergency (First Aid) inedical care may be rendered under this Act by any licensed physician,

e. Any member of a constituted medical staff of any Hospital may render care under this law while an injured employee remains a patient therein.

f. Medical care may also be rendered under supervision. Such supervision must be exercised by a licensed, registered, qualified physician. This supervision must be evidenced by written instructions for treatment and written records of condition. These shall be preserved for review by the Industrial Commissioner and (or) the County Medical Society. Under such medical supervision may be conducted first aid stations; industrial plant stations; dressings and treatments by nurses; physical therapy, and rehabilitation care.

g. Any person, firm or corporation who shall solicit for the professional treatment, examination or care of an injured employee or who shall make it a business to solicit in person or by circular or placards the employment of a physician or for a physician in connection with any claim under this chapter, shall be guilty of a misdemeanor.

Subd. 3. REMUNERATION.

a. Remuneration shall consist of a fair and adequate return to persons qualified to render medical care under this Act and such charges shall he based on the social and economic status of the individual and shall harmonize with the charges that prevail in the same community with similar treatment of injured persons of a like standard of living.

b, Remuneration for medical and surgical care—To Whom Payable. The fecs for all charges for all treatments rendered by a physician, surgeon, or other lawfully qualified person shall be payable only to the individual rendering the service or to his heirs at law.

c. All fees for such charges shall be paid within thirty days by employer or carrier or shall be protested to the Labor Department within thirty days of furnishing bill for some

d. Any person participating in the act of the division, transferance, assignment, subordination, rebating, splitting, or refunding, or who by any subterfuge is a party to such division, transferance, assignment, subordination, rebating, splitting, or refunding, of a fee for medical care under this Act shall be guilty of a misdemeanor, except that this rule shall not prohibit the payment of salaries by a qualified physician to others rendering medical care under his supervision as provided in Subd. 2, Para. f, of this Section.

Subd. 4

a. The determination of temporary, partial, total and permanent disability and of the degree or percentage of disability shall be the duty of one or more physicians qualified under the law, designated or accepted by the Commissioner or Referee silting in the case. Said Commissioner or Referee shall approve or appeal such determination. He has no authority to arbitrarily alter it.

b. In the end result after accident the following shall be used as a general guide for determination of degree of permanent disability:

Three factors are involved:

1. Function, or capacity to perform.

Union, or state of repair of parts.
 Contour, or external appearance.

Inasmuch as function is the most important part in any recovery from accident or disease, it should be assigned the highest percentage of value. Its suggested value is placed at 60%.

Union, or state of repair, naturally has an effect on ability to perform and also on appearance, but can be very imperfect while affording full function and satisfactory appearance. Its suggested valuation is placed at 20%. Contour or external appearance, plays an indirect part

Contour or external appearance, plays an indirect part in ability to perform and in a measure may influence function. Its suggested valuation is placed at 20%. However, if such disability of contour or general ap-

pearance is of such character as to reduce future em-

pearance is of such character as to reduce future employability its percentage should be increased.

Illustrative example: If in a given case F is only half perfect, allow 30% disability. If union or repair is half perfect, allow 10%. If appearance is three-quarter perfect, allow 5%. The end result then is 30 plus 10 plus 5 or 45% disability. Details of evaluation are to be based on "Accidental Injuries" by Kessler, or an equally authorizative text authoritative text.

Functional disturbance may be estimated by this scale regarding the following:

Flexion, Extension, Abduction, Adduction, Supination, Eversion, Inversion, Apposition, Rotation, Grip, Locomotion, Mastication, Audition, Vision, Articulation, Sensation, Co-ordination, Urination, Defecation, and other measurable capacity of function.

c. Appeals concerning the determination of temporary, partial, total, and permanent disability and of the degree or percentage of disability may be obtained upon appli-cation by the referee, employer (or carrier), or the em-ployee. The determination in such appeals shall be rendered by a Medical Advisory and Appeal Board of three physicians appointed by the Commissioner upon recommendation of the County Medical Society in the County where employee resides or elects to be heard. A fee of Ten Dollars shall be payable to said County Medical Society for each case reviewed, Five Dollars to be paid by appellant and Five Dollars by the Department of Labor. When appeals are too numerous for one Board to manage two or more Boards may be so designated. The decision of this (or these) Board (or Boards) shall be final but only as regards the determination of temporary, total, partial, or permanent disability, or the degree or percentage of disability. Whenever a County Medical Society fails to nominate a Medical Advisory and Appeal Board in accordance with this section of the Law within a reasonable time, the Medical Society of the State of New York shall nominate said board. d. Expert Opinion. The Industrial Board or an Ap-

peal Board may avail themselves of a written opinion of an expert upon the examination of a claimant with the approval of the Commissioner of Labor, who shall also direct the making of compensation for such service, the payment to be the fee usual for that service in

the community.

e. Whenever a case is re-opened the review and rejudgment of determination of degree of disability may be obtained upon order of the Commissioner of Labor after application by the Referee (who judged the case) or by employer or by employee. This review or rejudgment shall follow the course herein prescribed for the primary determination of disability. (Subd. 4, Para. a and Para. c.)

f. Awards by the Labor Department shall be determined in accordance with the medical evidence as here-

in prescribed.

Subd. 5. The determination of consequential accidents (old law sec. 2, subd. 7) and abnormal physical conditions "arising out of employment" shall be a duty of the Medical Advisory and Appeal Board, subject to the approval of the Industrial Board.

Subd. 6. Arbitration of bills for medical care. Employer (or carrier) and physician shall arbitrate all contested bills for medical care. In such arbitration there shall be two officially designated representatives of his County Medical Society and two physicians chosen by the employer (or carrier). In case of an equal division in votes of these representatives, the physician of the Labor Department who sits as presiding officer of the Board shall be entitled to a vote. The decision of this Board of Arbitration shall be final.*

Subd. 7. Hospitals operated by a City of more than

50,000 inhabitants as Charity Hospitals, Municipal or General Municipal Hospitals and maintained by taxation of the people, may treat only emergency cases under this law and these only as long as the emergency exists, except in localities where there is no other available Hospital provision.**

Subd. 8. It shall be possible for a person having a physical departure from normal resulting from congenital or acquired causes to waive his rights or those of his heirs to compensation for disabilities arising out of or related to aggravations or reactivations of the same.

The physical facts justifying the waiver must be concurred in by the prospective employee and a physician licensed to practice medicine under Article 48, Section 1251 of the Medical Law of the State of New York, the waiver to be certified to by the Commissioner of Labor of the State of New York. It shall be the responsibility of the Commissioner of Labor to ascertain that the individual seeking employment under the conditions of the waiver understands the facts contained or implied therein and if such a person be a minor, that one of the parents or a guardian of such minor shall have been informed in person and shall have affixed his signature to suitable number of duplicate copies thereof. No such waiver shall prevent an individual from claiming compensation not attributable to an aggravation or reactivation of the impairment waived against, but in which the existence of the impairment plays a part in delaying recovery or modifying the final result.

Subd. 9. No physician whether or not employed by the Department of Labor in any capacity whatsoever can serve both as a witness and as advisor to the Commissioner or Referee at a hearing. Serving in one capacity he is forever disqualified to serve in the other manner in the same case.

Subd. 10. The C-4 Forms shall be completed in triplicate within within 20 days by any qualified physician who attends a case under this Act. One copy shall go to the Labor Department, one copy to the employer or carrier, and one copy shall be retained by the physician. For each service rendered in completing C-4 Forms in triplicate (not carbons) the qualified physician shall receive a fee of Two Dollars (\$2.00) to be paid by the employer (or carrier).

Subd. 11. Failure to comply with either the literal or implied meanings of the Law regarding the provision for treatment by the employer or the acceptance of treatment by the employee may prejudice the immediate or ultimate result. Upon request of the aggrieved party, employee or employer (or carrier) the question of the degree of this prejudice shall be determined in exactly the same manner as the determination of the degree or percentage of disability—Subd. 4, para. a, and appeals may be taken from the primary decision in accordance with the appeals. with the regulations set up in Subd. 4, para. c.

Subd. 12. Whenever it results to the employee that accident impairments occur which have a definite permanent compensation value, which according to the opinion of the employer's (or carrier's) physician or physicians, may be corrected by reconstructive surgery and the employee objects to such reconstructive surgery, the employer is permitted to request the Department of Labor to secure the opinion of two or more of the Department's physicians to decide whether or not the opinion of the employer's physician or physicians should prevail. The employer or employer (or carrier) may appeal the decision of the Department's physicians thus rendered and this appeal shall be decided by the Medical Advisory and Appeal Board in precisely the same manner as prescribed for the determination of degree of disability as described in Subd. 4, para. c. If the decision on appeal

^{*}County Society can discipline unreasonable members. Secure justice for membership.

^{**} Note: The overhead of treatment under Workmen's Compensation Law should not be paid by the municipal taxpayer.

favors the desire of the employee this decision shall be final. If this decision supports the contention of the physician or physicians of the employer (or carrier) and the employee still refuses the reconstructive treatment, the allowance for permanent disability shall be paid for a length of time approved by the Industrial Board but in no case shall the Board allow such payments to continue for more than two years nor shall the rate of payment be increased over that previously determined. In this last instance this decision including the allowance and time limit shall be final,

Subd. 13. A committee on Discipline shall be appointed by the Commissioner. This Committee shall consist of eight qualified physicians. The Conunistioner shall appoint the members of this Committee selecting them from a list furnished as follows: Two members shall be chosen from each of the eight district branches of the Medical Society of the State of New York by the District Branch organization. One of each two thus chosen shall be appointed to membership of this Board. The functions of this Committee shall be to receive charges, conduct hearings, and make recommendations to the proper authorities in any case of formal complaint and filing of charges against a qualified physician, such complaints or charges purporting to show professional or other misconduct in connection with medical service rendered under this the Workmen's Compensation Law. Each appointment as member of this Committee shall be for two years. However, the original appointments shall be so made that four members shall serve one year and four members two years. Thereafter the system of two vear appointments shall prevail. Any physician found guilty of neglect, misconduct, deceit, or gross unfuses may be suspended from participation and privileges of rendering medical care under this Law by the Committee on Discipline.

19. Recommendation. — That the House of Delegates records its disapproval of any extension of the number or nature of compensable diseases beyond those already enumerated in detail, Section 3, subdivision 2, of the present law.

Public Health. Individualized Medical Service by Public Agencies

- 20. Our studies here have lead us to realize more fully the rapidity of the expanding program of individual medical service developed under the guise of Public Health. Thus the Public Welfare Law or Social Welfare Law and the Public Health Council have been carefully studied. The Commissioner of Social Welfare was invited to attend a conference with us and answered twenty-two previously prepared questions. His complete knowledge and thorough understanding of the Law proved most instructive. The following paragraphs contain a summary of information and opinions afforded by the Commissioner.
- 21. Perused and viewed from the standpoint of any public spirited citizen who is interested in the state-wide problem of providing medical and surgical service for the sick poor, this Law is notable for its lack of vision, provision and teeth. Its reference to and planning for the medical and surgical care of poor patients is summarized in a few lines, the most important of which says "a physician or physicians shall be appointed by the

County Commissioner." The law does not refer to the State or County Medical Society. It does not suggest that many physicians may share in the care of the indigent. It merely provides that such eare may be given and that the supervisors or other local authorities may appoint a physician for this work. These being the facts, let us do honor to the leaders in those County Medical Societies who, by their initiative, wisdom and diplomacy, have brought into practical completeness almost perfect workings of an ideal Public Welfare Law which has never been written. And this result has generally unanimous local and state-wide approval. The State Society has helped magnificently in this work through its modern Public Relations Committee, conceived by men of vision, manned by men of vital wisdom.

However competent, the Commissioner of Social Welfare is almost helpless in attempting to control the State's adventures in Social Welfare. The operation of medical relief from the Social Welfare Law is entirely in the hands of local welfare commissioners. The Law does not say to the local officials what to do, how to do it, when to do it, when to pay, and it does not say the Department shall do this and the Department ear-not impose penalties. In other words there are no teeth in the law. It is entirely operable by local groups of politicians. Until the law is changed, the only way to improve service to the needy and provide for reasonable compensation to the doctors is by persistent, diplomatic, publie spirited efforts on the part of the local County Medical Society to confer and arrange with the Welfare Officers. In other words, the success of the present law depends upon local understanding and cooperation.

23. Such understanding and ecoperation has developed in some of the counties and your Committee has in hand the complete arrangements made in some of these counties. The Suffolk County arrangements seem to approximate the ideal. Nassau and Oncida Counties recently adopted a somewhat similar plan.

24. In Ontario County the contract between the County Society and the Supervisors for the care of the indigent of that county for 1932 resulted in a net return to the doctors of \$.16 on the dollar for their services. The effects of the depression brought unusual demands in the second half of the year. The experiment is continued for the year of 1933. The Supervisors, keeping faith with their previous agreement, have inereased from \$3,000 to \$5,000 the budgetary allowance to cover the care of the indigent of that county for the year of 1933. This Committee offers its congratulations to this local county society for its initiative in undertaking this experimental work to determine the facts upon which to determine the proper budgetal allowance for indigent care.

- 25. Members of the Committee have addressed three well-attended meetings on this subject in widely separated parts of the State. There has been a definite gain in understanding this Law, certainly outside of the metropolitan area. The metropolitan counties are not affected by the Social Welfare Law because of their exclusion from its provisions in accordance with the socalled "Home Rule Law." This fact means that 7,900 doctors of the State are not affected directly or indirectly by the Social Welfare Law. We believe this is not desirable. We believe the taxpayer, the needy citizen and the physician would all profit if the metropolitan counties were included under a revised Social Welfare Law which would provide amply for medical service to all the needy and compensation to the physician who performs the service for the county.
- 26. A completely new medical chapter is needed in the Law with specific provisions and detailed instructions for all commissioners and workers. The supervisory and directing power of the Commissioner should be increased. Power should be his to compel local commissioners and officers to abide by certain definite principles. Power of removal of incompetent, inhumane, unfair or dishonest commissioners or local officers should be vested in some State officer.
- 27. Recommendations.—That the Medical Society of the State of New York recognize the need of a new chapter in the Public Welfare Law which shall specify the principles upon which medical care shall be given to the indigent and provide for reasonable compensation to the physicians rendering services. We recommend that the said medical chapter should contain the provision that the indigent persons thus served should have the privilege of choosing the physician to whom they should go and that the principle of hiring one or two lowest bidders to do all of the medical work in the County is not good public policy.
- 28. Recommendation.—That the Medical Society of the State of New York instruct the Committees on Public Health, Public Relations and Economics to join in the drafting of a desirable chapter as suggested in recommendation paragraph 27 and such other amendments as would seem best for the welfare of the people of the State of New York, including New York City.

Geib-Vaughan Detroit Plan.

29. In accordance with our recommendation in paragraph 97 of our 1932 Annual Report and the instruction of the House of Delegates at its last session, a thorough study of the Geib-Vaughan Detroit Plan of Public Health work has been conducted. A sub-committee of two visited Detroit in company with a special emissary from President Heyd, to observe the practical workings of the Plan and to ascertain cardinal faults if any

existed. Their report with printed materials was convincing as to the results obtained. This Plan has been in operation four years. Success, technical, psychological and civic has crowned its efforts. Tax-payers profit in lessened use of public Substantial reductions in mortality and morbidity have been recorded. All of the people have access to the measures thus far introduced by this scheme. All the physicians of the county society are earnest workers in the scheme. Graduate medical education is furnished and de-Physicians are recompensed for treatment of the indigent from public funds. This scheme is an evolution not a revolution. Geib-Vaughan Detroit Plan of Public Health work has thus far been applied only to preventive measures, namely diphtheria prevention, small pox prevention, early detection of tuberculosis and the combating of venereal diseases. This is to be extended to other measures in preventive medicine. Cooperation of the physicians has been practically unanimous—1,100 physicians become health officers. Post-graduate lectures and courses in preventable diseases are enthusiastically attended by the physicians. District nurses in house to house visitations discern needs and point out to parents what should be done regarding their family and explain to what doctors' offices people may go regardless of their capacity to pay. In the longest experimental demonstration (diphtheria prevention) the mortality is reduced, the incidence of protection has been elevated by large percentages in each age class, the expenditures for this work have been definitely reduced, and yet every physician has been paid something for every service rendered. An interesting incident and objective in the operation of this Plan is the abolition of public clinics and the savings of maintenance costs. The Detroit idea is that the work is done better and at less cost when distributed among the physicians' offices than when centered in the public clinic. After careful study we believe that the principles of the Detroit Plan can be practically applied to all forms of the practice of preventive and curative medicine. The leaders and statesmen of our profession should devote themselves to determining how and how rapidly this Plan can be developed and what are the initial steps. It is our opinion that 20 to 30 years will be required to complete such a program and that the traditional devotion of the profession to the welfare of the people may be a guarantee of performance. The Detroit Plan demonstrates the efficiency and economies of decentralization in medical practice. In other words, the people receive more service and the cost to the tax-payer is less than for previous less effective services, partly because of the abolition of health centers and clinics. Centralization may be an ideal manner in which to conduct hard business. Decentralization provides convenient access to an individual doctor's office obtainable by all the people regardless of economic status. With the abolition of all free and part-pay clinics, the hospital in each district, having its facilities available for any patient or any physician in that district we would have cooperation of all physicians in best of service to all the people, and tax-payers would pay less. The Detroit Plan has elevated the quality of service in every feature it has undertaken. The quality and its aim to universal application are its strong points.

- 30. Recommendations.—That the Geib-Vaughan Detroit Plan of Public Health Work be cordially and completely approved by the Medical Society of the State of New York and that the State Society initiate active efforts to introduce this principle of participation of the medical profession in Public Health work, both preventive and curative, throughout the State of New York.
- The Promotion and Practice of Preventive Medicine. In one respect we find the recommendations made by all of the committees on social trends, medical education and costs of medical services, to be in harmony with those of organized medicine. This is in the call for greater understanding, greater development and more active service in Preventive Medicine. This Committee is in accord and we believe that the situation calls for renewed, vigorous and unremitting effort. Preventive Medicine has vital economie features. The return of medical service to the physician's office, from the public clinie as accomplished by the Detroit Plan; the return of the School Medical Inspection service as undertaken by the Bronx County Medical Society; and the efforts of this Society to promote periodic health examinations at the physician's office are all cases in point. These are only three of the many economic features in the field of Preventive Medicine, yet Preventive Medicine transcends the scope of this Committee. It affects our public relations and our medical education. It affects every department of medical science and medical practice. We believe that organized medicine should guide medical and lay opinion in this field.
- appoint a committee representing the several branches of medical science and practice to study the field of Preventive Medicine, and in association with the several standing committees, to prepare and present authoritative information and recommendations in a coordinated report calculated to insure the development of this work in accordance with sound principles of medical organization and practice.
- 33. Public Health Council.—The appointment, organization and functions of this body have been studied. Recent regulations promulated have been considered. The membership of our Society should be alive to the potentialities

- here smoldering. Flames may never develop. If they do they will destroy much that the people need and more that has been the outcome of activated high-minded scientific ideals for a century past.
- 34. Several closely typewritten pages have been collated by a sub-committee. Many astonishing findings are reported. A suggestive outline for consideration follows: The Public Health Law defines the Public Health Council as consisting of the Commissioner of Health, together with six other members all appointed by the Gov-Excepting for the Commissioner, the term of appointment is six years. Of the six members, at least three must be physicians experienced or trained in sanitary science and one must be a sanitary engineer. This body has power, by a majority of vote (for example, a vote of any three members, plus the vote of the Commissioner himself) to establish, amend, and repeal sanitary regulations, without discrimination against any licensed physicians. Such regulations, formally passed by the Public Health Council and approved by the Commissioner, become the Sanitary Code. The Sanitary Code is then defined, in the same chapter of the Public Health Law, in these words: "The Sanitary Code may deal with any matters affecting the security of life or health or the preservation and improvement of public health in the State of New York."
- 35. Your Committee brings to your attention the faet that the Public Health Council, an appointive body, is really a legislative body, inasmuch as the Code it has adopted, and from time to time changes by amendment, is the law of New York State. Nor do any of its regulations need any approval, nor are they subject to any veto from an elective officer, although they are subject to the veto of another appointive officer, the State Commissioner of Health, who is himself a member of the Council.
- 36. Your Committee brings to your attention the fact that, although the Public Health Law provides that there must be three physicians in the membership of the Council, or, counting the Commissioner of Health, a total of four physicians in a membership of seven, there is no provision that any one of them shall be a practicing physician. As a matter of interest, there is at the present time only one practicing physician on the Public Health Council.
- 37. Your Committee brings to your attention the broad powers conferred upon the Public Health Council. It may pass regulations, and these regulations become the Sanitary Code, and the Sanitary Code becomes the law of the State, as long as the regulations deal with "any matters affecting the security of life and health or the preservation and improvement of public health." This is a fairly broad definition, and under it the

Council can, as it already has done, pass regulations governing blood transfusions, regulations as to what physicians may or may not perform public health bacteriological examinations, regulations as to what physicians may or may not examine pathological specimens removed at operation or autopsy. The breadth of the powers of the Council are further shown by chapters in the Sanitary Code dealing with the use and storage of x-ray film (a noxious gas or fire hazard) and others dealing with the handling and transportation of tetra-ethyl lead.

- 38. The Public Health Council, it is apparent, can, when they deem it necessary for the security of life and health, pass regulations affecting the manner of the private practice of medicine, and the regulations they pass will be law. This will be so regardless of the fact that the regulations were made by an appointive body, and a body in which it is not essential that a single practicing physician act as member.
- The only protection afforded the medical profession against a perfectly legal but nevertheless rigid and onerous regulation by the Public Health Council is the phrase in the Public Health Law which provides that the regulations of the Council must be "Without discrimination against any licensed physicians." This phrase has not prevented the Public Health Council from discriminating against licensed physicians in its regulation requiring credentials additional to a medical license for health officers and laboratory directors, and additional procedures for those licensed physicians doing blood transfusions. Will it be a protection when the Public Health Council passes regulations covering additional credenx-ray operators, obstetricians, for surgeons? Such regulation of the privately practicing medical profession may be necessary, but is it wise and proper for it to come from a body which is appointive, and in whose membership the medical profession as a practicing entity is not adequately represented?
- **40.** Thus the dangerous implications and potentialities under this provision of the Public Health Law are:

Public Health Council is an appointed body answerable to no one and no one can alter their rules and regulations.

These rules and regulations which may define, limit, abrogate and otherwise interfere with the practitioner of medicine as licensed by the State can handicap service to the public.

These promulgated rules and regulations become laws of the State.

The Council can publish their personal views and sentiments at the State's expense and so propagandize their personal desires regardless of benefits to the citizenry or discrimination against physicians.

The appointive powers have apparently disregarded the value to the State of the knowledge acquired by the licensed physician with years of experience and considerable eminence in his profession.

41. Essentially the questions which arise are: Is the Public Health Council so constituted as to render the fullest service in Public Health to the citizenry of the State of New York?

Should an appointed body of any character possess such broad powers?

Should the Public Health Council have the power to adopt regulations affecting the private practice of medicine, in view of the fact that in so doing it is exercising a legislative function, a function of the Legislature of the State of New York.

42. Recommendation.—Your Committee recommends that the constitution, powers and potentialities of the Public Health Council be referred to the joint consideration of the Committees on Public Health, Public Relations, and Economics with legal counsel for report at the next Annual Meeting of the House.

State-Aided Hospitals

- 43. Considerable thought has been given to the status and professional organization of County hospitals receiving State Aid. The difficulties and cross-purposes affecting Lewis County have been considered. A sub-committee of two has carefully investigated every phase of the situ-These gentlemen have visited Lewis County and Albany and have conferred and corresponded with all concerned officers. A representative of the State Health Department has reported a personal investigation of the hospital and detailed the evident faults in operation. As in other portions of the Public Health Law, the Commissioner considers that his duty ceases when he finds that the County hospital receiving State aid is operating in accordance with rules recognized as standard by the American College of Surgeons and accepted by the Medical Society of the State of New York.
- 44. Recommendations.—1. That the Medical Society of the State of New York considers that complete local autonomy in the administration of a State-aided County hospital is a policy of doubtful justice and efficiency.
- 2. That representatives of the Committees on Public Health, Public Relations and Economics be instructed to study the relations of the Health Department and Department of Social Welfare to State-aided County hospitals and offer recommendations which would tend to increase efficiency and justice in the administration of these institutions.

THE POOR, CHARITY, EXPLOITATION OF PHYSICIANS

45. General Municipal Law.—The House of Delegates at its Annual Meeting in June, 1932, unanimously adopted a resolution offered by the Erie County Medical Society condemning certain phases of the General Municipal Law. The insufficiency in our administrative organization and our indifference to the general welfare of the public and our profession are nowhere more clearly illustrated than by the fact that this law has been on the statute books since 1909 and that it has required the recent sad experience in one of our most active and progressive centers of civilization to demonstrate how unjust and preposterous the law is. By it the State provides that any county, town, city or village can erect and maintain an institution for the charitable and noncharitable treatment of disease in direct and underhanded competition with the professional man whom it (the State) has licensed to do this work. Moreover, it gives the governing board of any county, town, city or village the right to appoint the staff of physicians and surgeons who must work without remuneration for such hospital thereby entering into unfair competition with their colleagues while they and their colleagues are being taxed for the maintenance of said hospital. The ramifications of evil which may and do emanate from the actions of this law brings injustice and extra cost to every tax-payer in any community where a hospital is actively operating under this statute.

46. Examples: A sound, home-owning citizen with an influential friend in politics has a pain; surgeon diagnoses cholecystitis, advises operation. Patient sees politician friend, who says, "I will see the superintendent of the hospital, don't worry about money." Admitted to hospital, no charge for maintenance, no charge for operation. Community and surgeon cheated 1 Another example: the vicious tendency developed in the minds of normal, upright and always self-supporting families which creates the feeling that the government should somehow or other give them something for nothing. In other words, this law increases the tendency which we see more and more in our times for a type of people hitherto independent to claim dependency upon public funds. This means the development of a type of psychology among the hitherto solid section of our people which must sooner or later result in deterioration of character, broad and diffuse in its distribution.

A third evil is that taxes are unreasonably increased in the provision of care for non-indigents. At the same time the indigent may be deprived of adequate care, thereby.

It becomes a definite encouragement to the growing tendency of making county, city, town and village offices attractive to a type of clever,

characterless individuals who can live well on account of the favors they can distribute to certain voters. In other words, this law encourages the development of government by privilege.

The irony of the law: the physician who has prepared himself to care for the sick and who has been licensed by the State, must pay his share of the tax to create and operate institutions which shall make it impossible for him to conduct his work with the remuneration that the State expected him to get when it licensed him.

Thus has been established by the power of the law inequitable competition between doctors who are willing to serve the local institution without pay (or with pay as the case may be) and their colleagues who must depend upon their private practice in order to exist.

47. Certification of the Indigent .- In paragraph 102 of our 1932 Report is a brief reference made to the certification of the indigent supported by the approved recommendation - paragraph 104a. This has been a matter of study during the current year. As far as indigent persons or families are concerned in private practices of physieians, it seems just and best to all concerned that the physician alone is to be the judge as to whether he will or will not serve these indigent persons without remuneration and without referring them to the Commissioner of Charity or Commissioner of Welfare. A different situation is created when the individual applies for free care at a hospital or any other institution, the maintenance of which is provided for either by taxation levied upon the citizens of the community or by contributions from the more or less prosperous members of the community, as is the case in hospitals conducted by the self-perpetuating Board of Trustees who alone are responsible under law for the eare of people and care of monies which are contributed by trusting benefactors. (Here the problem of who shall be awarded free treatment is more complex because of multiplied relationships.) We have felt the injustice of being compelled by a Board of Trustees, or Board of Managers or city government or county government to care for people who are receiving all hospital treatment and care without cost to themselves when we knew that these people owned more property and had more means than we ourselves or perhaps than most of the doctors in the community. It is true that if every person who requested free treatment were asked for a certificate of indigency, undoubtedly physicians would benefit to the extent of many thousands of dollars per town. This, however, will be a mere by-product of principles which involve justice to all tax-payers. It only needs to be mentioned to be self-evident that if all of the tax-payers of a community are taxed every year a certain extra percentage because people who are not indigent are to receive treatment at the city or county

hospitals there is an injustice to every tax-payer in the community. The benefactor of a hospital presents hundreds or thousands of dollars to trustees of the hospital for the benefit of the community poor. If any fraction of the income or principal is spent giving free care or partly free care to people who are well able to meet the ordinary bills of maintenance in hospital and of medical and special care the trustees are unjust to that Anon that benefactor will realize how false were these trustees and will cease to be a benefactor and perhaps cease to love his fellowman as he did before this injustice was done him. In other words it is for the benefit and righteous justice of every tax-payer and every contributor in all communities that every person who receives free treatment at any hospital should be certified as indigent. The facts are so elementary to the tax-payer and so hazardous will be the results of the pauperism of the great middle class of our people, who are not only in numbers but in physical, mental and spiritual qualities the solid part of our civilization, that justice to the rank and file compels our action. This attempted pauperism which has already been well started may well lead to a national or world-wide degeneracy because it is, undoubtedly, a fact that men and women begin to slip as solid characters when they cease to fully realize their responsibilities.

- 48. Recommendation.—That the Medical Society of the State of New York approve of and urge the "Certification of the Indigent" as an essential qualification for securing medical care without charge from any county, town, city, or village or in any hospital. out-patient department or dispensary or any other institution affording sick care incorporated under the laws of the State of New York.
- 49. Application of the principle of the certification of the indigent has been deemed by your Counsel and your Economics Committee the best method of amending the General Municipal Law of 1909, as amended by the Laws of 1922. are cognizant of the fact that evil and injustice has not always resulted from the utilization of the General Municipal Law before cited. It is the intent that this application of the certification of the indigent as an amendment to the General Municipal Law should in no way interfere with operation of any portion of any general municipal hospital affording private or semi-private accommodations or private wards where patients pay the stipulated hospital charges. It is expected to be applicable to that portion of such hospital which is devoted to the free treatment of patients.
- 50. The text of the amended sections and paragraphs, as proposed, follows:

"Section 129. General powers and duties of superin-

"5. Receive into the hospital, under the rules established by the board of managers, any person in the

county, town, city or village who is sick or maimed or injured, and who is in need of hospital care, provided said person has complied with the provisions of the article relative to admission to such hospital. The said superintendent may also receive persons from without the county, town, city or village, provided there is a vacaney in the hospital and provided the reception of such persons does not interfere with the proper care and treatment received by persons from the county, town, city or village, and provided that such person has complied with the provisions of this article relative to admission to said hospital."

51. Section 130 of the General Municipal Law, as amended by the Laws of 1922, Chapter 265, in effect March 25th, 1922, is to be amended as follows:

"Section 130. Admission and maintenance of patients. Except in cases of emergency, and then only as long as said emergency exists, the superintendent of such hospital shall not admit any patient nor permit any patient to remain in such hospital unless the patient presents at the time of admission a certificate from the county commissioner of Public Welfare for the county welfare district in which such person resides, or the City Commissioner of Public Welfare for the city welfare district in which such person resides, certifying that such person is wholly unable to pay for hospital and medical care. No employee of such hospital shall accept from any patient thereof any fee, payment or gratuity whatsoever for his service, except that physicians and surgeons rendering services under the Workmen's Compensation Law shall receive the allowed payment for services so rendered."

52. There shall be added to Article 6 of the General Municipal Law a new Section to be known as Section 130a, which shall provide:

"Section 130a. Indigent persons only shall be received or treated at public general hospitals. Subject to the provisions of this article, no persons shall be received or treated at such hospitals except one who is wholly unable to pay for hospital and medical care."

53. To Article 10 of the Public Welfare Law there shall be added a new Section, i.e., Section 85a, which shall read as follows:

"Section 85a. Duty to provide certificate of indigency for persons applying to public general hospitals. It shall be the duty of the commissioner of the city or county public welfare district to investigate the financial status of any person residing in such district and applying for admission into any public general hospital. If after such investigation said commissioner is satisfied that such person is wholly unable to pay for hospital and medical care, then he shall issue a certificate to that effect. Such certificate shall be valid evidence of indigency only for a period of six months from the date of the issuance thereof."

54. Recommendation.—That the Medical Society of the State of New York approve of the amendments to the General Municipal Law and Public Welfare Law as proposed by the Committee on Economics in collaboration with the Counsel.

Veterans' Administration Hospitals

55. Many hundreds of physicians gladly served the country in the World War. Many of these are active participants in the work of organized medicine. These and all of the members of the Medical Society of the State of New

York should be interested in the problem of what should be done with the Hospitals of the Veterans' Administration. We feel that there has been an excessive dispensing of national bounty in the form of hospitalization. We believe that organized medicine should speak vigorously in opposition to the use of these hospitals in direct or indirect competition with the practising physicians of the United States, many of whom are the same men who volunteered at considerable sacrifice to care for the soldiers during the War

56. Our tenets in regard to the use of Administration Hospitals are as follows

a Use should be free and generous to all those who were disabled dinring the War or are suffering from any disability which is of such nature as to make it at all likely that it originated during their term of service

b The use of the Veterans' Administration Hospitals should be available for all service men whose physical and financial need of such hospitalization is certified by their attending physician or surgeon or any physician or surgeon who is qualified to so certificate the veteran Such physician's certificate is hould be a definite

requirement

Veterans who are self-sustaining and solvent and who suffer from ills not connected with service should not be hospitalized or treated at the expense of the Government any more than they should receive groceries, or clothing, or housing, or coal or light at the Government's expense If they do, the Federal Government is entering into direct and rumous competition with physicians licensed to practice medicine in the various States composing the Federation

e The use of Veterans' Administration Hospitals to hospitalize other than veterans is morally, and perhaps legally, a wrong to the Government, to all taxpayers and causes the Government to enter into the same type of competition with physicians as referred to in paragraph b

We recognize while littering the above that inistales have been made in building veterans hospitals so large as to provide several times the needs of the veterans now or ever in that section Such hospitals should be disposed of by the Government, a moderate capital loss being more sensible than a huge loss from earing for those who will be better citizens if they care for themselves

d After the same manner the Government me the excessive inclusion of other critizens among those eligible for admission, is entering into competition with many hospitals organized and maintained by the tax-payers of the county, town, city or village, or organized and maintained by benefactors, or by the action and cooperation of genetous citizens. In this way the Government is abolishing the insefulness of institutions set up

by citizens who again have to pay takes to support the veterans' hospitals. Is the Government to succeed if it injustly abolishes the usefulness of citizens or institutions who should be supporting it? Will the citizenty long accept excessive repealed taxation for the same item?

- 57. We hope that all of our members will use all of the influence which they can possibly summon to promote the abolition of these nefari ous practices which are immical to the interests of millions of high type citizens Plans should be made to close veterans' hospitals as rapidly as is possible. None should be necessary after 25 to 30 years In all probability the number of beds can at present be justly reduced to one eighth of present capacity and still serve the disabled vet The most important consideration in erans well connection with this question is the growing policy of Government pauperization of heretofore self-respecting and self-supporting people taste of free hospitalization, free coal, free light, free provisions, rapidly deposes the sense of responsibility in the impority of minds thief concern of the individual thiis affected is not how to contribute to his day and civilization ill he possibly can, but how he can get as much as he possibly can for nothing, without work
- 58. Our tenets in regard to the use of Administration Hospitals were sent to the Committee on Economics or the officers of each of the 60 County Medical Societies in the State. With these was enclosed the request that the County Society addressed should write to as many of the list of 36 Senators, Congressmen and other officials as possible stating the opinions of their Society. Cordial State wide response and cooperation were secured.
- 59. Recommendation We recommend that the Medical Society of the State of New York ratify and approve the tenets outlined by the Committee on Economics, and that the Secretary be instructed to forward a record of this action to the list of Government officials furnished by the Committee on Economics

Financing of Sichness

60. In October, 1931, the Committee on Economics recommended to the Executive Committee a set of proposed principles and a program for the supervisory regulation of firms who collect doctors' bills and finance sickness by small loans. This recommendation was disapproved In the 1932 Report to the House of Delegates the Committee on Economics reaffirmed its belief in the need for such regulation and supervision provided that nothing shall be done to involve this Society in any way in any financial responsibility. On recommendation of the Reference Committee, the House of Delegates referred this back to the Committee to be resubmitted to the

Executive Committee. Accordingly, this Committee made the following recommendations in its November, 1932, report to the Executive Committee:

"The approval of the following paragraphs to be set up as regulations to be accepted by any concern dealing with bill collection for physicians or the financing of sickness who desire to voluntarily accept advisory supervision by the Economics Committee or other designated commission of the Medical Society of the State of New York:--"

"1. Submit to the Economics Committee a brief history of the firm and brief statement with names of all principal owners (10 per cent or more).

"2. A statement of previous business connections of each director or owner and to advise us immediately of all subsequent changes

of ownership.

"3. Names of banks where the firm does business, financial references, and other business associates.

"4. Name of bonding company, amount and date of bond which covers each employee who handles money.

Statement of what there is to guarantee stability of the firm and to guarantee performance of contract (a bond or its equivalent).

"6. Supply the Committee on Economics with copies of all printed forms and advertising matter as or when issued and agree to immediately delete or recall anything which is not approved by the Committee.

7. Contract between doctors and firm must be standard and submitted for approval of the Committee. No change shall be made without

the approval of the Committee.

Present financial statements showing: "a. Resources and liabilities on date of

application for listing. "b. Total amount of new account items of previous year. Total of money paid to doctors on that amount. Total which is still held collectable. Total abandoned as noncollectable.

- "c. File with this Committee monthly, quarterly, or yearly statements, as required, showing total of new accounts received; total of payments to doctors; total remaining in process of collection; total of abandoned accounts; number of cases carried to court action; and such other items as may be specified.
- "9. Agree to confidential review of books and records of the firm by the Committee or a representative thereof. A certified public ac-

countant may be employed by the Committee at the company's expense.

"10. Agree to accept judgment of all issues and be bound by the decision of a Committee. the latter to be of or appointed by the Economics Committee.

They shall provide credit information "11. service to all physicians registered by them for

service.

"12. Each and every firm accepting a place on the list shall agree that this listing is for the information of members of the medical profession and shall in no way be used for commercial publicity.

These regulations to be subject to revision, addition and extension to conform to the provisions of the Massachusetts Small Loan

"14. That nothing herein implied or otherwise stated shall be taken to involve the Medical Society of the State of New York or any of its component county societies in any responsibility or liability for the performance of contract by any firm.

That it shall be within the prerogative of any local or State Committee to remove any name from such listing without claim, liability or protest on the part of a firm so removed."

62. All of these recommendations were disapproved by the Executive Committee on January 12, 1933, in the opinions as quoted.

"Paragraphs 1 to 15. It is questioned if these recommendations dealing chiefly with the supervision and control of commercial agencies financing sickness and collecting bills for physicians are really within the functions of the Committee on Medical Economics as detailed in Chapter X, Section 5 of the By-Laws. It is doubted if the Committee has the facilities for such service or if the State Society desires to assume the responsibilities which would be incurred by the Committee in this way. In consequence the approval of the recommendation is not advised."

- 63. Recommendation: This Committee reaffirms its belief in the recommendations expressed in paragraph number 61 of this report. We recommend their adoption by this House of Delegates.
- In addition to the above recommendations and extending them the following recommendations were also forwarded to the Executive Con-
- "(a) We recommend that each County Society be urged to provide its members with a listing of the local facilities for the handling of deferred payments for such patients as may prefer to meet their obligations to the doctor out of earned income."

"(b) We recommend that the Society be urged to follow the regulatory provision set forth in the preceding paragraph [61] and that they shall list no firm for banking duties who is not willing to accept the supervisory and investigative functions of the State Committee on Economics and the right of this Committee to make inquiry and investigation into the conduct of their affairs."

"(c) We recommend that all firms who propose to serve in the capacity of bill collectors shall be required to file a bond to guarantee the security of any money collected and the safe delivery of it to the physician for whom the collector acts as

an agent."

- 65. The Executive Committee disapproved of these recommendations as "not advised for the same reasons as stated in the consideration of recommendations—62."
- **66.** We recommend that the House of Delegates approve of the recommendations contained in Paragraph 64.

67. Some of the firms in the new field of banking have agreed upon the reau of Supervision for

The purpose of this Bureau is to establish machinery for policing of the activities of its mem-bers. This Bureau will establish rules of conduct, censor contracts, advertise, etc., hold adequate bonds guaranteeing performance of contracts and security of monies entrusted to any member or employee in the course of its business and to guarantee to the profession that each member firm is ethical, reliable and stable. All of the provisions and principles for safeguarding the ethics of professional service and the security of funds and the fair treatment of patients, proposed by this Committee, are incorporated in the by-laws and rules of this new organization. It will be governed by a small directorate board on which there will be professional representation. Further, an advisory council, composed of twenty members will be chosen from the organized professions, ten physicians of recognized standing and five dentists, pre-eminent in their profession, will be invited to sit in this council. Each of the five metropolitan county medical societies will receive an invitation to be represented by its treasurer. All matters relating to the ethical conduct and publicity and the general character of the activities of this Bureau of Supervision will be subject to the approval of this Advisory Council. Complaints which cannot be adjusted to the satisfaction of either the laity or the profession by the financing companies or the Burcau of Supervision may be appealed to and settled by this Professional Advisory Board. It is the belief of this Committee that when this principle of handling accounts receivable has been generally adopted that the professional-patient relationship will suffer less frequent vexations from unpaid obligations.

68. National Health Plan. The Committee has carefully investigated the officers, stock-

holders, the copyrights, trade marks, and the plan and operation of the National Health Plan, Inc., of Providence, R. I. We have met the President, Hamilton E. Cray, and discussed everything pertaining to the Plan with him and have seen the opinions of a number of prominent public men concerning it. This Plan provides for regular weekly deposits in a savings bank of the patron's own choosing and is essentially a copy of the Christmas Club applied to provision for sickness instead of Christmas presents. At the end of fifty-two weeks the participant receives a check for the full amount with interest which he can deposit in his savings account or ne can withdraw part and deposit the rest in his savings account or the account can go on for another year. Furthermore, it is provided for if during the year an illness supervenes and hospitalization or surgical operation prove necessary, the participant may give to the doctor or doctors rendering services an order for collecting the amount of the fund at the end of the period when it shall have become paid up. During the year 1931, a bad year, Six Hundred Million Dollars were deposited in this manner in Christmas funds. If such an amount could be awaiting the needs of illness to pay physicians. hospitals, dentists and nurses, we believe that the public would have a healthier attitude toward medical service. However satisfied we may be with the organization of the Plan and the personnel of it's organizers and even though the only transactions in money would take place between depositors and their own savings banks, we recognize the wisdom of the dictum that the Medical Society of the State of New York should not endorse or approve of any firm.

69. Recommendation: That the House of Delegates approve of the principle of thrift as portrayed in the National Health Plan, Inc., or in any other similar plan which seems to be honorably conducted through legally constituted banking facilities. This Society does not assume responsibility for the acts of any other corporation.

70. Brattleboro. In accordance with the action of the House of Delegates on Paragraph 121 of the 1932 Annual Report, a member of this Committee visited Brattleboro, Vermont. In this village there are organized two benefit insurance schemes to provide nursing care and for hospital and surgeons fees. Its availability is limited to the stratum of ten or fifteen per cent of the population immediately above the indigent in financial abilities, families and persons self-supporting and solvent in ordinary healthy years but rarely able to make provision ahead for illness.

The plan has proven successful because there are no administrative or overhead costs, no salaries for investigators and other insurance company impedimenta. The beneficiaries of this insurance are limited to the range of neighborhood

acquaintance. The benefits are limited. The patient must pay the first \$30 of the cost of each sickness for which he is hospitalized. Thereafter payments up to three hundred dollars are guaranteed if needed. Surgeons fees are paid. The nursing service is assured at exceedingly low rates but there is always some participation on the part of the insured. The initial premium charge has been found to result in a deficit and moderate increases will be instituted. The philosophy of the supporting Thomas Thomson Fund, as voiced by Mr. Bradley, Trustee, is to encourage and not paralyze self-reliance. "We help those who help themselves" is really an expression of the prin-This plan of mutually organized health insurance is limited in the possibility of its application to larger urban or metropolitan communi-

Physicians and Courts

71. The re-referred matters contained in Paragraphs 141 to 149 inclusive in the 1932 Report, under the caption "Physicians and Courts" have been studiously considered and on December 8, 1932 we reported to the Council, the following recommendations:

"a. The introduction of an amendment to the Civil Practice Act creating a new classification of witnesses, adding to the old order that of 'medical witness,' the qualification of such witness naturally conditioned upon the license to practice medicine in the State of New York.

"b. That such amendment shall provide for an adequate minimum fee to be paid in compensation for physicians' appearance in court.

"c. That such amendment shall release the physicians and surgeons of active practice from the ordinary, conventional subpoena; such witnesses to be subject only to the command of the court and shall appear as witnesses for the court instead of partisan witnesses for one or the other side in a legal claim.

"d. The approval of all recommendations in paragraph 149 of the 1932 Report (after deleting all of Section F.). Such recommendations being contained in sections a, b, c, d, and e of said paragraph, except that in section d the personnel of the four representatives shall read as follows: "The Counsel of the Society and three physicians who have been admitted to the Bar in the State of New York."

72. In regard to the first three recommendations, the Executive Committee has ruled:-"Desirable as is the proposed legislation, its consideration is questioned in that it would be class legislation and in a letter dated November 19, 1931, our legal Counsel so rules."

"The matters relating to the above recommendations will therefore need reconsideration and re-presentation in new form." In regard to the other recommendations contained in Paragraph

149, exclusive of Recommendation f, the Executive Committee ruled "That such provisions were submitted to the House of Delegates at the last session and not adopted. It is advised that they should not be considered at this time by the Executive Committee and that the Committee on Economics be asked to re-submit them to the House of Delegates if they desire to do so."

73. Recommendation: Therefore, after a careful understanding with our Counsel, we re-recommend the following:

a. That this House of Delegates approve of the principle of Compulsory Arbitration of automobile accident case claims.

b. That we approve the inclusion of a doctor on such arbitration board.

c. That the Secretary of this Society transmit the expressions of our approval to Justice Frederick E. Crane.

d. That the House of Delegates request Justice Edward Lazansky of Appellate Division to include in the "permanent committee" to receive suggestions helpful to the betterment of the general administration of the law, four representatives from the Society. These representatives shall be Counsel of the Society and three physicians who have been admitted to the Bar in the State of New York.

Lien Law. On December 8th, 1932, we recommended for re-consideration by the Executive Committee the proposed amendment to the Lien Law of the State of New York, previously offered in November, 1931, disapproved by them at that time, presented to the House of Delegates in the last sentence of Paragraph 149 in June, 1932, and by them re-referred for further consideration and re-presentation. The proposed amendment follows:

AN ACT: To amend the lien law by providing therein that a hospital, physician or nurse rendering medical aid and service to any person injured as the result of an accident has a lien upon the patient's cause of

The People of the State of New York, represented in

Senate and Assembly, do enact as follows:
Section 1. Chapter thirty-eight of the laws of nineteen hundred nine, entitled: "An Act in relation to liens, continued nine, entitled: "An Act in relation to liens, continued nine, entitled laws" stituting chapter thirty-three of the consolidated laws," as amended, by chapter five hundred fifteen of the laws of nineteen hundred twenty-nine is hereby amended by inserting after section one hundred eighty-four a new section to be section one hundred eighty-five to read as follows:

Section 185. Lien of hospital, physician and nurse, A hospital, physician or nurse rendering medical aid and services to any person injured as the result of an accident other than a claim for compensation under the Workmen's Compensation Law has a lien upon the patient's cause of action, claim or counterclaim which attaches to a verdict, report, decision, judgment or final order in the patient's favor in whosover's hands they may come and the lien cannot be affected by any settlement between the patient of the pa ment between the parties before or after judgment or final order. The court upon the petition of the hospital, physician or any property of the hospital, physician or any physician physician or nurse may determine and enforce the lien. Section 2. This act shall take effect May 1st, 1933.

This has been approved by the Executive Cominities on February 9, 1933

75. Recommendation That the Medical Society of the State of New York approve of this proposed amendment to the Lieu Law

76. In Paragraph 161 of our 1932 Annual Report, there was recommended the appointment of a committee to make a study and recommendations on "organization and administrative machinery to make the collective thought of this organization more effective"

As amended, this recommendation passed with instructions to the Council to publish its report by December 15, 1932 We have not found this pub

hshed report

77. We re iterate the opinion that a reason able measure of economic security to physicians and to the State Society is dependent upon the full utilization of our administrative powers There is needed the means of creating and maintaining perfect understanding, solid progressive action and cooperation Under present conditions two or three committees may be undertaking the study of the same law and its effects or to initiate reforms or in some other way respond to the demands of our membership. We believe that all standing committees should understand what the other committees are doing The Executive Com mittee should understand what the committees are doing and there should be means of correlating work so that its results will come to the Society more promptly and more forcibly

78. In 1932 we did not presume to suggest what such a plan should be The general misunderstanding of the aim of Paragraph 161 and the request of officers lead us to present examples of what might be done in this way. A designated member of the Executive Committee and a designated member of each of the other standing committees might attend each meeting of a standing committee. This would keep the Executive Committee and all standing committees in complete knowledge of the work undertaken by each of the standing committees. Overlapping and reduplication could be avoided and economies of time and money obtained for the Society.

79. Another way in which committee work could be better correlated and economies practiced would be to secure the appointment of a Special Committee of four in addition to the President of the Society who would constitute a policy planning and hason committee. One of this committee could attend all meetings of standing committees and report in a monthly meeting to the President so that the developing of matters under consideration could be understood. We believe that the natural reaction against change is enhanced by the surprise which accompanies its first presentation.

80. These plans are suggested as illustrations

of what might be accomplished by reorganization of our committee work. Changes far more radical than these might be effected with profit to the organization. We are inclined to regard evolution as superior to revolution. Some measures similar to one of the above illustrations might well serve us at this time.

81. Recommendation We recommend that a committee of five be elected by the House of Delegates or appointed by the President with in structions to devise and present a plan of committee organization to be reported to the Council not later than December 15, 1933, and the action of the Council thereon to be published in the New York State Medical Journal at the earliest possible date

82. In conclusion we wish to express our gratitude and appreciation to those who have materrilly assisted us in our work during the current President Heyd has attended four of our sessions and aided its with good advice and valuable suggestions Dr Peter Irving, Assistant Secretary, has visited us and offered constructive information Our Counsel, Mr Lorenz J Brosnan, has attended a meeting and has held numerous conferences with the Chairman and other members of the Committee IIIs advice has been invaluable Commissioner Johnson sat with us through the larger part of a busy meeting and answered a large number and variety of questions concerning the Social Welfare Law and its oper He did this with the utmost frankness, ations good humor and intelligence Dr Emil Koffler attended one of our meetings at which time he accepted a commission from us to make an exlinustive study of the clinics of the metropolitan district following out a plan outlined by the Committee and approved by the Executive Committee Dr Alec Thomson who was appointed a special emissary of the President to investigate the Geib Vaughn Detroit Plan attended one of our meet ings and rendered his report concurrently with the reports of our sub committee of two His report is in our files as valuable evidence Joseph Lawrence Executive Officer of the So ciety, has attended four meetings and has given us cheerfully of help and understanding

Respectfully submitted

REPORT OF THE COMMITTEE ON LEGISLATION

To the House of Delegates:

Gentlemen:

Your Committee on Legislation cannot submit you a final report of its activities for the year, owing to the fact that the Legislature is still in session at the time this report must be written, but it is pleased to report that it is unusually busy studying bills of proposed amendments.

The committee, acting upon your direction, has been enlarged by two members, and in accordance with a program developed this year, has divided the state so that each member holds himself more or less responsible for the active cooperation of a certain number of chairmen of county committees.

During the fall, your chairman held a conference with the president of the Second District Branch and representatives of the four County Societies in that Branch, at which time a program of intensive cooperation was developed. It was agreed that when adverse legislation is pending, a most effective way of combatting it is by enlisting the aid of influential lay persons. order that a group of such persons should be available for use this winter, it was decided to ask the chairman of the Legislative Committee of each of the County Societies to enroll, prior to January 1st, as many influential persons as possible and a printed form for collecting such enrollments was devised. Later it was decided that this form should be published in the county bulletins of the Second District and in the State Journal. The matter was presented to the Executive Committee and approved by it.

The committee has met monthly since the convening of the Legislature and, with the Executive Officer, carefully studied each bill, advising him of the committee's approval or disapproval.

Thus far the efforts at legislation differ somewhat from previous years, but are directly in line with the spirit of the times. No cult bills have been introduced, but many amendments proposed that would have an economic bearing on the practice of medicine. The antivivisection society has split and, accordingly, we have two dog bills to oppose; the usual one and another more rigidly drawn, introduced by Assemblyman Bernhardt Mr. Bernhardt announced during of Buffalo. the summer that he had been requested to introduce a bill and proposed to do so. He has also introduced a resolution calling for an investigation of the laboratories of the state. Lately, however, he has expressed himself as unwilling to push either of the two measures; he is satisfied that it was a mistake on his part to sponsor such legislation.

Among the other bills to be acted upon are the omnibus health insurance bill of previous years; several amendments to the Workmen's Compensation Law making all diseases and disabling con-

ditions arising out of industry, compensable; another that would create a state fund to carry all of the state's insurance, and one authorizing a survey by a legislative committee of the administration of the Compensation Law. All of these are being opposed by the Executive Officer at the direction of your committee.

A number of bills have been introduced modifying or attempting to reconstruct the narcotic drug law. Several of these are modifications of the model offered by the A. M. A. Your committee is in sympathy with the object of these amendments, but cannot see that they carry sufficient improvement over the present law to make

their enactment urgent.

Two bills have been introduced relating to hospital dispensary administration, one denying hospitals the right to collect fees for dispensary services and another creating a committee to authorize dispensary patients; and another closely related, authorizing the creation of a committee in each welfare district to certify the indigent who should be cared for. The approval of these bills has been directed.

Two hospital lien bills have been introduced. Neither of them makes provision for the physicians. With the assistance of Mr. Brosnan, each of these bills has been amended so as to include the physicians and the Executive Officer has been directed to have one or both of these amendments introduced.

The chairmen of the country committees have been unusually cooperative thus far this year. Many more comments have been received at the Albany office and Dr. Lawrence reports that the chairmen of the Senate and Assembly committees, as well as members of these committees, are receiving many more letters from their constituents advising action on bills, than in previous years.

As was stated above, the session is probably not more than half concluded at the time of writing this report and many things may happen before adjournment.

We are keeping the chairmen of the county committees advised of the status at Albany through our weekly bulletins and special bulletins when such are necessary. We are also sending copies of all important bills to the chairmen, and other material which comes before the Legislature or is issued by it that may be of interest or assistance to the county committees.

We have not had a meeting of the chairmen of the county committees in two years and quite a number of new men have come into positions since then. It would be well to consider a conference as a part of next year's program. Certain of the older chairmen have held conferences with their committees and their Senators and Assemblymen since election. The results of such conferences are so satisfactory that the committee has

recommended that each County Society arrange such conference.

Owing to the necessity of submitting this report at this time, the committee asks the privilege of submitting a supplementary report after the adjournment of the Legislature or at the time of the meeting of the House of Delegates, if the Legislature is still in session.

Respectfully submitted, HARRY ARANOW, Chairman

February 15, 1933.

REPORT OF THE COMMITTEE ON PRESS PUBLICITY

To the House of Delegates:

Your Special Committee, with a budgetary allotment of one-hundred dollars, has been unable to do more than cogitate. There is great uncertainty in the minds of the profession regarding the entire problem of publicity, whether it be through the press, through the radio, through the lecture platform or through other methods, such as pamphlets, specially prepared articles, and the like.

Your Special Committee believes that progress in acquainting the public with what the medical profession is doing, has done, and is prepared to do, requires an adequately administered department of the State Society, if the profession is to make headway in overcoming the cynicism of the public and lay organizations against the medical

profession.

Widespread publicity has been given (and threatens to be expanded under a high-powered public relations counsel) to the Report of the Committee on the Costs of Medical Care. The medical profession finds itself with no real means of combating such propaganda, as we depend upon an untrained, unprepared, heterogenous group of volunteer publicity men. Chairmen of press reference committees, public relations committees, public health committees, and so forth, in the different county societies are busy practitioners of medicine. They willingly give of their time. They make a valuable contribution that is negated by lack of personnel and facilities to carry on, to do the detail work, and to establish and maintain contact.

Your Committee believes that if the medical profession is to make progress in the field of public health and relations it must be done as an organized body. As such, we must be able to follow the methods carried on in other state societies and in the American Medical Association, whereby health information, discussions of current medical problems, contact with public agencies and the like are recognized as an imperative need

—a need that is to be met by budgetary allocation sufficient to employ personnel capable of presenting medical information in a medical style that will be as readable as the usual content of the news column.

Your Committee on Press Publicity reports having received very few inquiries concerning problems within its field. Many of the county societies have in one form or another released a considerable amount of medical news. Some have conducted radio broadcasts. Others have provided lecturers on medical subjects.

Your Committee finds that some State Societies and a number of county medical societies throughout the country conduct an active medical information service in one form or another; that more of this type work is being done elsewhere than in the State of New York; that where done most successfully it is administered by the organization sponsoring the work through a department employing paid personnel—and not dependent upon volunteer service of active practitioners.

The Committee recommends that the Medical Society of the State of New York establish in the administrative office a division of publicity, in cluarge of an employee who would be responsible for the preparation and dissemination of medical information, and the organization of a department that would render service to the county societies desiring assistance for dissemination of local information of a similar character.

The Committee recommends the discharge of the Special Committee on Press Publicity, unless the House of Delegates, in its wisdom, determines that the State Society establish the recommended division of publicity and wishes the Special Committee to be continued for the purpose of assisting in the organization.

Respectfully submitted,
ALEC N. THOMSON, M.D.,
Chairman,

February 15, 1933.

REPORT OF THE FIRST DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The First District Branch of the Medical Society of the State of New York, comprises the Counties of New York, Bronx and Richmond in the Metropolitan District, and Rockland, Orange, Westchester, Putnam and Dutchess in the lower Hudson Valley. The County Societies are all active in carrying out the policies of the State Society.

The Annual Meeting was held at the Rockland Golf Club, Sparkill, on October 14, 1932, and was well attended. In the morning, many members enjoyed a round of golf. Luncheon was served at 1 p.m. followed immediately by the business meeting and election of officers. The Nominating Committee presented its report as follows:

For President—C. Knight Deyo, M.D., Pough-keepsie; for First Vice-President—Samuel J. Kopetzky, M.D., New York; for Second Vice-President—Edward C. Podvin, M.D., Bronx; for Secretary—Isidore J. Landsman, M.D., Bronx; for Treasurer—John T. Howell, M.D., Newburgh.

The report of Nominating Committee was ac-

cepted in its entirety and the candidates were duly elected.

Short addresses were then made by Dr. Charles D. Kline, President of the First District Branch, Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, and former Presidents Dr. James E. Sadlier and Dr. Orrin S. Wightman. The absence of Dr. Frederick H. Flaherty, President-elect, and Dr. Daniel S. Dougherty, Secretary of the State Society, was much regretted.

The following scientific program was then in-

troduced:

"Neurogenic Basis for Abdominal Sign Symptoms," by Edward M. Livingston, M.D., New York.

"The Adrenals in Health and Disease," by Max

A. Goldzieher, M.D., Brooklyn.

"Compulsory Health Insurance Abroad," by Emil Koffler, M.D., Bronx.

These papers were very interesting and instructive and greatly appreciated by all present.

Respectfully submitted,
CHARLES D. KLINE, President.

Committee was ac- February 15, 1933.

REPORT OF THE SECOND DISTRICT BRANCH

To the House of Delegates: Gentlemen:

Your councillor for the Second District Branch has made one or more official visits to each of the four component County Societies composing the Branch.

The Branch has held two meetings. One was in June at the Lawrence Country Club. The Annual Meeting was held November 17th at the Garden City Hotel. The descriptive reports of these meetings have appeared in the New York STATE JOURNAL OF MEDICINE.

The Branch Executive Committee has met for the purpose of planning the Branch activities.

The Chairman of the component County Society Committees of Legislation and Economics have met with the respective State Chairmen for the purpose of arranging for unified action.

Each component County Society has continued to carry on the various activities reported upon by the Branch Councillors for the past few years.

The President and the Secretary of the Branch have attended all committee meetings and conferences of the Branch.

A good deal of thought has been given by the officers and groups of members to the elaboration of a plan for the Branch, which if possible of accomplishment would provide administrative machinery, that would enable physicians of Long Island to actively participate in the community efforts directed toward disease prevention and health preservation and promotion.

Respectfully submitted, Louis A. Van Kleeck, President.

February 15, 1933.

REPORT OF THE THIRD DISTRICT BRANCH

To the House of Delegates: Gentlemen:

The twenty-fifth annual meeting of the Third District Branch of the Medical Society of the State of New York, was held at Sharon Springs New York, on Wednesday, September 16, 1931 and the twenty-sixth annual meeting in Loomis

Sanatorium, Loomis, New York, on Wednesday. September 21, 1932. The first being held at an extreme northern and the latter at the most southern part of the District. Despite that both these places are somewhat difficult of access for some members, the attendance was in each in stance surprisingly good. That the programs

were remarkably attractive and meritorious was largely due to the care exercised by the executive committee in the selection of the speakers, they being guided in this by the counsel of our State Society's Executive Officer, Dr. Joseph S. Lawrence.

I wish personally to thank each speaker for his contribution to the success of these meetings and also the manager and the physicians in charge at Loomis Sanatorium for the whole hearted welcome and entertainment we received there.

A very notable event in the history of the Branch occurred on the evening of October 28, 1931, when the Albany County Medical Society celebrated the one hundred and twenty-fifth anniversary of its foundation. The meeting was held in the dining room of the De Witt Clinton Hotel and the excellent dinner, the welcoming speech of Mayor Thatcher and the inspiring addresses of Drs. George W. Crile, William D. Johnson and Charles K. Winne combined to make the occasion a most memorable one.

The Board of Supervisors of Columbia County met on December 20, 1932 and voted to organize a county health department. This is to include the city of Hudson, the approval of which had been previously obtained. The board of health (three of whom are physicians and members of the county medical society) will appoint a full time commissioner of health and initiate the work of the department.

We are pained to record the death of two of our intimate friends and ex-presidents of the 3rd District Branch—on September 15, 1930, Charles P. McCabe of Myocarditis and on December 25, 1932, Luther Emerick of Pneumonia. They served faithfully and well and deserve to be held in loving remembrance.

Respectfully submitted,

HERBERT L. ODELL.

President.

February 13, 1933.

REPORT OF THE FOURTH DISTRICT BRANCH

To the House of Delegates— Gentlemen:

Owing to a rather prolonged illness during the early part of the year, and to the fact that the district covers a large territory making the meeting places of the various component societies rather inaccessible at times, I have been unable to fulfill all my obligations. I have, however, been in fairly close touch with the counties in the neighborhood of Schenectady and know something of the work of the others and feel justified in reporting that they and the branch as a whole are doing their part in supporting the State organization and in making its work worth while.

The Annual Meeting held in Schenectady in October was well attended and apparently successful. The Clinical and Pathological demonstration at the Ellis Hospital on the morning of the first day was an innovation which, judging from the amount of favorable criticism received, was of real benefit to those members whose contacts with hospitals are infrequent.

On Wednesday morning, October 12th, the group was entertained at the Research Laboratory

of the General Electric Company.

Respectfully submitted,

FRANK VANDER BOGERT, President February 15, 1933.

REPORT OF THE FIFTH DISTRICT BRANCH

To the House of Delegates:

Geutlemen:

The Fifth District Brauch of the Medical Society of the State of New York, comprising the counties of Herkimer, Jefferson, Lewis, Madison, Oneida, Onondaga, and Oswego, held its twenty-sixth annual meeting October 4, 1932, in the Elks Club, Oneida. About one hundred twenty members attended. Dr. D. H. Conterman, President of the Medical Society of the County of Madison, made the opening address.

The scientific program follows:

"Present Day Status of Allergic Disease," T. Wood Clarke, M.D., Utica.

"Correlation of the Symptoms and Pathology of Arteriosclerotic Heart Disease," Harold E. B. Pardee, M.D., New York City.

Luncheon at Hotel Oneida. Introduction of Guests.

"Surgical Measures for the Relief of Intractable Pain," illustrated with lantern slides and moving pictures, Byron Stookey, M.D., Neurological Institute, New York City.

"Some Indications for Plastic Surgery," Leon

E. Sutton, M.D., Syracuse.

"Study of Surgical Complications, Incidence and Treatment," Murray MacG. Gardner, M.D., F.A.C.S., Howard N. Cooper, M.D., F.A.C.S., Watertown.

Entertainment for the visiting ladies was provided by the wives of the Oneida physicians.

After luncheon, at the nearby Hotel Oneida, guest speakers, officers of the State Society were introduced: Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, Dr. Frederick H. Flaherty, President-elect. Dr. Thomas P. Farmer, Chairman of the

Committee on Public Health and Medical Education, Dr. O. S. Wightman, Editor-in-chief of the New York State Journal of Medicine; all of whom spoke on matters of interest to the Society and of importance to physicians generally.

EDWARD R. EVANS, President.

February 15, 1933.

REPORT OF THE SIXTH DISTRICT BRANCH

To the House of Delegates:

Gentlemen:

The report of the Sixth District Branch follows:

There has been no outstanding event in the District during the past year. Economic problems of medicine have been given greater attention than ever before. The report of the Committee on the Cost of Medical Care has been of especial interest, because of the location in the District of the subject of one of their studies and reports. Otsego County held a very interesting historical meeting at Cooperstown.

The 26th annual meeting of the Branch was held at Binghamton in the Masonic Temple on Tuesday, September 27, 1932. One hundred were registered as attending. The day was not propitious.

Mr. Homer Folks, Secretary of the State Charities Aid Association of New York City,

spoke on "The Health Program Recommended by the State Health Commissioner." Dr. Hugh Auchincloss, Professor of Clinical Surgery at the College of Physicians and Surgeons in New York City, demonstrated with the aid of numerous charts and slides "Finger and Hand Destruction and Reconstruction Problems."

Luncheon was served in the same building. President Heyd was unable to be present. Among the speakers were President-elect Dr. Frederick H. Flaherty of Syracuse, Secretary Dr. Daniel S. Dougherty of New York City, and Dr. Orrin S. Wightman, Editor-in-chief of the State Journal

In the afternoon Dr. Louis C. Kress of the State Institute for the Study of Malignant Disease at Buffalo by aid of four lantern demonstrations discussed most thoroughly "Bone Lesions."

Respectfully yours,
S. B. BLAKELY, President.

February 15, 1933.

REPORT OF THE SEVENTH DISTRICT BRANCH

To the House of Delegates—Gentlemen:

The Annual Meeting of the Seventh District Branch was held on September 29, 1932, at Clifton Springs Sanitarium, with an attendance of about two hundred.

The Scientific Program includes a paper by Dr. George W. Crile of Cleveland who talked on "Indications for, and end results of, Denervation of the Adrenal Glands." Dr. Crile's paper was discussed by Dr. William D. Johnson of Batavia, also by Drs. Carl Huber and William Dean of Rochester. Dr. William P. Healy of New York gave a paper on "Cancer of the Uterus." This paper came in for lengthy discussion. Those Physicians taking part in the discussion were Dr. Kress of Buffalo and Drs. W. D. Ward and W. E. Bowen of Rochester. Dr. Warfield T. Longcope of Baltimore talked on "The Differentiation of Chronic Pyelonephritis from other forms of Bright's Disease." Dr. Longcope's paper was discussed by Dr. Reifenstein of Syracuse and Drs. Haller, Miller and Kohr. of

Rochester. Dr. Foster Kennedy of New York talked on "Head Injuries." Dr. Kennedy's paper was discussed by Dr. Ward Williams of Rochester, also by Dr. Johnson of Batavia and Dr. Armstrong of Canandaigua. There were also short talks by Dr. Daniel S. Dougherty and Dr. Orrin S. Wightman of New York and Dr. Frederick H. Flaherty of Syracuse. It was a very enthusiastic meeting.

Representatives from the following Counties in the District were present: Monroe, Wayne, Cayuga, Livingston, Ontario, Seneca, Steuben, Yates and Schuyler. Seven County Presidents out of the nine Counties represented were present. The greatest number of physicians came from Monroe and the least number from Schuyler.

The dinner which was served in the dining room of the Sanitarium was attended by one hundred and forty and was most enjoyable.

Respectfully submitted, James M. Flynn, President

February 15, 1933.

REPORT OF THE EIGHTH DISTRICT BRANCH

To the House of Delegates: Gentlemen:

As President of the 8th District Branch, permit me to submit the following report of our activitics during the last year.

In June we had a splendid meeting of the Executive Committee in Buffalo. There was a thorough discussion of the economic conditions confronting our component societies.

In October our annual meeting was held at Leroy, with an attendance of one hundred and

twenty. The program included Dr. Goodrich on Medical Economics, and Drs. Leahy, Joslyn and Hurxthal of Boston on Scientific Problems.

During the year Erie, Niagara and Chautauqua Counties have had difficult problems to face, and have done courageous work in meeting these difficulties.

Respectfully submitted,

RAYMOND B. Morris.

President.

THE ANNUAL REPORTS

This issue of the Journal is of unusual size, for it contains the annual reports of the officers and committees, and also the programs of the major features of the Annual Meeting. These programs are more varied and extensive than ever before and contain new features

which will make a strong appeal to the members.

The Annual Reports are printed in the place of the usual scientific department of the Journal; but they may properly be considered to be scientific papers on the subjects of Administrative Medicine and Medical Economics. In fact they are practical dissertations on the subjects, setting forth what the Medical Society has done during the past year in its own peculiar field of organized medicine. These reports have a value which is not only for the present, but will be increasingly evident as years go by. The extensive entrance of the State Medical Societies into the field of civic medicine dates back only a decade, and yet even now the beginnings of those activities are in dispute, for no one could foresee their phenomenal growth or recognize those which were destined for wide development.

The Annual Reports are constructed along the lines of the private practice of a family doctor treating a patient, for each deals with

its subject in three sequences:-

The Examination
 The Diagnosis
 The Treatment

The regardent The report deals with facts, and sets forth the activities of the society and its committees. It describes the workings of the Society and its contacts with other organizations, especially those engaged in education and social betterments. The reports present an excellent picture of the policies of the Medical Society of the State and those of the Counties, and the aspirations of their members.

The reports also comment on the conditions which are found, and diagnose their strength and their weaknesses, their trends and their accomplishments. Their diagnoses are peetiarly accurate and enlightening, for the leaders in the Medical Society of the State of New York have the benefit of the broadest experience that is available in any State, but they are also spurred by lay health organizations and survey groups that are centered in Greater New York. The judgments set forth in the reports of the officers and committeemen of the Medical Society of the State of New York are sane, enlightening, and judicial.

The reports also suggest lines of treatments in the form of recommendations for the House of Delegates to consider. The action of the House will be the policy of the Medical Society of the State of New York and the County Societies during the coming year. The State Society does not assume an attitude of dominering over the county societies and their members, for it encourages them in original

activities and demonstrations.

The Annual Reports are of personal interest to every member of every County Medical Society, for their approval or criticism will be expressed by County Society representatives who are expected to prepare themselves for their duties by reading the reports with care.

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Enforcement of Medical Practice Law: This Journal of March, 1908, contains the inaugural address of Dr. J. Riddle Goffe, President of the Medical Society of the County of New York, in which he was unduly optimistic in the control of quacks when he says:

"We have been criticised somewhat for taking the fines that come from convictions in courts, and we all feel that we would like to avoid this if it were a possible thing. Most cordial relations have been established with the District Attorney and his office, and also with the Police Department. It is our hope and expectation that we may now shift a large part of this work upon

the shoulders of these two city departments and secure sentences of imprisonment instead of fines. The permanent effect of such sentences would be more far-reaching. A thousand additional members of our Society, through their dues, would aid vastly in securing this desired end. To further this project I have taken the responsibility of appointing a special committee, whose duty will be to select and solicit new members.

"The new medical laws of the State are going to make it easy to put the specious medical quacks and the advertising medical institutes on the run, and a vigorous campaign against them is now being instituted."

MEDICAL PROGRESS

Arterial Obliteration .- By means of experiments on dogs F. Albert demonstrated that obliteration of the principal artery of a member produces an active peripheral vasodilata-tion which in arterial ligature introduces an additional menace of peripheral gangrene. In an earlier work the author had already established that obliteration of the principal vein has an opposite effect, producing active peripheral vasoconstriction, with an appreciable increase of the peripheral pressure. of the satellite vein will, therefore, by the active vasoconstriction it produces, compensate at least in part the vasodilatation following ligature of the artery. The vasodilatation is independent of the carotid sinuses, and is not the result of a local vessel irritation at the point of closure. It is also independent of the greater part of the nervous system, and in fact resists all nerve sections performed at the root of the member. It remains identical after spinal anesthesia, and is still present, though in less degree, after anesthesia of the sympathetic ganglionic chain. Modifications of intravascular pressure play very little part in these vasomotor responses to arterial oblitera-It appears that the principal cause of vasomotor reactions must be found in physiochemical modifications established in the composition of the peripheral blood and of the interstitial fluids under the influence of a cellular metabolism vitiated by arterial obliteration. This would lead to the appearance of substances with determined vasomotor reactions, which act directly upon the walls of the small vessels and capillaries and produce the reactions in question either directly or through the intermediary of the sympathetic peripheral nerve terminations and by reflex-axonic mech-The existence and nature of these vasomotor products still remain to be formally established. Injection of an ultrafiltrate of the return blood of a limb suffering with certain peripheral sympathetic troubles seems to demonstrate in this blood the presence of vasodilator products. Thus in certain peripheral vasomotor affections of sympathetic origin there would be produced, or would accumulate, at the periphery products of metabolism capable of maintaining certain vasomotor reactions, once they have been set up. It is interesting to note that in different forms of physiopathic affections very different kinds of return blood can be withdrawn according to the affection, that is, each sample is always the same for the same affection. A simple transitory compression of the vessel might be able, through the opposite vasomotor reactions set up by obliterations of arteries and veins, to compensate in the one or the other direction certain vasomotor troubles. The author has already obtained very definite results along these lines.—Lyon Chirurgical, November-December, 1932.

Gastrocardiac Manifestations as Sequels of Left-sided Phrenicotomy.—On the basis of a wide study of the literature and of 106 leftsided and 126 right-sided phrenicotomies personally carried out, H. Jahnke undertook to determine whether permanent or late injuries could be demonstrated as a result of this procedure. In 21 cases in which the operative purpose was achieved there was an especially high position of the diaphragm afterwards, this being in some cases a handbreadth above its original place, independently of the length of the removed nerves. In but few cases, however, was there any striking displacement of the median organs of the body from their median position, and these were predominantly due to a marked cirrhotic tendency, occasionally with extensive induration of the pleura and pericardium. But in none of these cases were there any serious subjective discomforts of the heart or any gastrogenous disturbances. The pain from a feeling of pressure after eating, a sense of nausea, etc., complained of by a number of patients disappeared completely a few weeks after operation, returning only in exceptional cases, and then but transiently. Dyspnea upon movement and the subjective cardiac manifestations somewhat more frequently observed were due, in some cases, to extensive and destructive pulmonary tuberculosis, as well as to the narrowing of the half of the thorax resulting from the high position of the diaphragmatic arch, which caused a correspondingly diminished lung surface; in other cases they were due to changes in the course of the blood stream in the pulmonary circulation. It is astonishing, however, to note how slight are the phenomena caused by these changes, often extreme, of topography of organs, especially of the heart and large vessels, provided the heart muscle and the vascular system are sound. Only in adipose types of constitution did a slight insufficiency of circulation exist, which was expressed in a tendency to air hunger and palpitation upon the slightest exertion. Such subjective cardiac manifestations were observed in a few of the author's

cases, and in 12 there were also transitory gastrogenous pains; but in none was there any permanent condition in the sense of a Roemheld complex. Although in most cases the time of observation has been relatively short, averaging only 4 months, Jahnke has been able to follow up 24 left-sided cases over a longer period, some as long as 8 years, without any persisting cardiac or gastric injuries being observed. Permanent or late injuries are, at any rate, so unusual that they need be given no special attention in the choice of cases.—Deutsche medizinische Wochenschrift, December 9, 1932.

Two Rapid Tests for Pregnancy.-In 1929 I. E. Markee showed that the rhythmical vascular changes in endometrial transplants onto the iris are arrested by follicular hormone. This suggested to him the possibility of using this modification of the uterine vascular rhythm as a test for the presence of follicular hormone in the urine of pregnant women. He has devised two ways of applying the test, namely, the direct and the indirect. When 20 rat units, per kilogram, of follicular hormone are injected into a rabbit, the color of the transplant is noticeably intensified, and within fifteen minutes the transplant becomes 20 per cent redder. In twenty minutes a slight irregularity of the cycle develops and the ratio of the time in vasoconstriction to that in vasodilatation is greater than 1:6; in thirty minutes the ratio is 1:10 or greater. These modifications continue until forty minutes after the injection, when the rhythmic vascular changes cease and the color of the transplant is comparable to that of 50 per cent hemoglobin. The color changes in the transplant are recorded by comparing the color with the colors in a Tallqyist hemoglobinom-The direct test is made by injecting the follicular hormone that has been extracted from 150 c. c. of urine by a method only slightly different from that of Frank and Goldberger (1930). A volume of 150 c. c. of urine has been taken because it is not possible to extract enough follicular hormone from that amount of urine from a nonpregnant woman to arrest the rhythmic vascular changes in the transplant, and because 150 c.c. of urine from a pregnant woman will yield enough of the hormone to have this effect. The main advantage of this method is that the diagnosis can be made forty minutes after the injection or two hours after the specimen of urine has been obtained. The indirect method consists in the intravenous injection of untreated urine from pregnant women. With this method the modification of the vascular rhythm is arrested in seven to eight and one-half hours after the injection and is similar in every respect to that following the injection of the follicular hormone. The direct test has the advantage that either gonadectomized or non-gonadectomized male or female rabbits may be used, and that the same animal may be safely used every third day. With the indirect test the same animal cannot be used oftener than every third week, since the injection of urine from a pregnant woman induces pseudopregnancy. Specimens of urine from 147 pregnant and 26 non-pregnant women were tested by both the direct and the indirect method and all of the diagnoses have agreed with the clinical histories.—Surgery, Gynecology and Obstetrics, January, 1933, 1vi, 1.

The Modern Conception of Nephritis, and Its Bearing on Certain Problems of Life Assurance.-Although a final conception of nephritis has not been reached, T. Izod Bennett finds that the last five years have seen an emergence, in many different countries, of an important agreement among a body of workers who have studied the subject deeply, concerning the major aspects of nephritis. In the classification of the varieties of nephritis it is more and more generally recognized that three groups are to be distinguished. Of these the central group includes the true inflammatory kidney diseases following acute infections. This great group of glomerulo-nephritis may be subdivided into a relatively benign group in which scattered foci of inflammation arise during an acute infection, and a second group in which the inflammation is spread diffusely through both kidneys. The latter group includes serious cases of nephritis, which begin usually as a streptococcus infection. In this group death occurs from uremia, cerebral hemorrhage or pseudo-uremia, according as the factor of glomerular destruction, or that of increasing hypertension predominates. In sharp opposition to this group two other groups are recognized: (1) Nephrosis, in which there is intense albuminuria without edema, hematuria, increase in blood pressure, changes in the retinae, or any tendency to uremia. There is no evidence of change in the glomerulus, but there are purely degenerative The prognosis changes in the renal tubules. in many examples of this group is relatively good. (2) Ischemic nephritis, of which the outstanding manifestation is hypertension. The main feature of the morbid anatomy is sclerosis of the kidneys and spleen, with hypertrophy of the heart. In this group death occurs more frequently from cerebral catastrophe or from cardiac failure than from renal failure. It is not to be supposed that there are no clinical difficulties as regards allocation of certain eases to this last group.

From the point of view of life insurance,

each of these groups presents a condition dangerous to life, but the degree of danger varies considerably. A point to be stressed is the extreme importance of accurate blood pressure estimations, and these should not be reserved for applicants in the last decades of life. Essential hypertension may appear at ages as early as twenty. The woman who has borne children should not be accepted for life insurance without careful consideration of her history and blood pressure. Careful examination of the urine remains of major importance, but observation of the specific gravity of urine which contains no albumin is superfluous. Oualified acceptance can usually be given with safety in cases of nephritis which, five years after onset, exhibit albuminuria as the sole evidence of disease. Mild degrees of hypertension, without albuminuria or cardiac involvement, with a systolic pressure below 180 and a diastolic pressure below 100, tend to be far too heavily loaded at the present time.— The Lancet, January 7, 1933, ccxxiv, 5706.

The Thyroid and Potassium Permanganate Treatment of Furunculosis.—W. Antony Ball states that the administration of thyroid in the treatment of boils has been successful. As boils are common at the time of puberty this is understandable, though all the successes are not at puberty. Again satisfactory results have been claimed by injections of collosol manganese; similarly alkalis have been given. Ball used bi-palatinoids, containing thyroid ½ grain and potassium permanganate ½ grain. It then seemed to him that these tablets might combine the properties of both thyroid and collosol manganese, with the added advantage that they are given by mouth, so he gave them together with his usual prescription: Ferric sulphate, 3 grains; magnesium sulphate, 30 grains; dilute sulphuric acid 10 minims: Fowler's solution, 2 minims, and chloroform water to make 1/2 ounce. Both the mixture and a tablet were given three times a day. The boils ceased with dramatic suddenness. He has now treated 12 cases of boils of all types with a similar improvement in every case. He feels that there is some connection between the oxidizing action of the potassium permanganate and the thyroid, and that they act by tending to sway the hydrogen-ion of the blood. The result may possibly be due to the antiseptic action of the potassium permanganate on the intestinal contents, but this does not account for the action of the thyroid. -Practitioner, January, 1933, cxxx, 775.

A Discussion of the Rôle of Arterial Thrombosis in the Visceral Diseases of Middle Life, Based upon Analogies Drawn from Coronary

Thrombosis.—Lewis A. Conner, writing in the American Journal of the Medical Sciences, January, 1933, clxxxv, 1, calls attention to the fact that whereas thrombosis in the arteries of the heart and of the brain is known to be common and is easy of clinical recognition, almost nothing is known concerning the symptoms of arterial thrombosis in the abdominal The failure to recognize this condiviscera. tion must be due in part to the inherent difficulties of diagnosis, but it is certainly partly due to failure to have the possibility of such attacks in mind and to have accumulated pertinent evidence. Conner has constructed a tentative framework for the diagnosis of arterial thrombosis in the several organs. Kidney-In a person of arteriosclerotic age, in whom there is no ground for expecting the discharge of arterial emboli, the occurrence of dull pain and tenderness in the flank, of more or less fever and leucocytosis, and of red cells and albumin in the urine (if absent previously) would seem to justify the diagnosis of thrombosis of the kidney. Spleen-Pain of the pleural type, fever, leucocytosis, tenderness, and perhaps muscular rigidity in the splenic region, with not infrequently a to-and-fro perisplenic friction sound, warrant the diagnosis of arterial thrombosis in this Pancreas-Pain in the epigastric or umbilical regions, with some tenderness, shock, fever, and leucocytosis, and probably nausea and vomiting-all symptoms which might be due to disturbances in neighboring organs. The simultaneous appearance of sugar in the urine, however, would go far toward justifying the diagnosis of arterial thrombosis. Mesentery—The symptoms of intestinal infarction vary greatly in character and severity. At the onset there is violent crampy pain, with nausea, vomiting, sometimes diarrhea and usually prostration, sweating and col-The vomitus and stools are frequently blood-stained. After a day or two the symptoms of paralytic ileus appear. There is probably some fever and leucocytosis in every case at some stage. If the diagnosis of intestinal infarction seems justified, it still remains to distinguish between three possible sets of causes—mesenteric venous thrombosis, arterial embolism, and arterial thrombosis. If internists and pathologists would correlate their findings in regard to arterial thrombosis in the abdomen, the lineaments of the respective pictures will gradually emerge from their present obscurity, much as have those of the diagnosis of coronary thrombosis.

Intravenous Pressure.—W. A. Brams, N. L. Katz, and W. J. Schutz present a new method, based on a new principle, for the determination

of intravenous pressure. They believe that it eliminates most of the objections to the older methods, and that it has the additional advantage of a sharp end-point which can be read without hurry. After placing the patient at rest for ten minutes in a horizontal or semirecumbent position, the arm and hand to be examined are supported by a pillow at a level which corresponds to the point of entrance of the vena cava into the right auriele. Following the suggestion of Eyster, this point is taken to be in the fourth interspace, at the junction of the anterior and middle third of the anteroposterior diameter of the thorax. The method itself is based on the principle that the superficial veins on the dorsum of the hand can be easily visualized in a darkened room by transillumination. The superficial veins then appear as black bands which can be obliterated by moderate pressure, and thus distinguished from shadows cast by ligaments. The mouth of a small glass funnel is covered by a thin rubber dam held securely in place by a thread tied tightly in a previously prepared groove near the rim. A small hole is then cut in the rubber dam, through which the vein to be examined is visualized, such a vein having been selected in a darkened room. The surface of the rubber dam is covered with rubber cement, and the funnel is placed on the dorsum of the hand so that the vein is seen through the aperature in the rubber. Moderate pressure causes the rubber to adhere to the skin, making an air-tight seal. The tip of the funnel is then connected by rubber tubing to a suitable water manometer, so graduated that the pressure may be read in millimeters of water. The room is again darkened, and a light placed over the palmar surface of the hand visualizes the vein within the aperture of the rubber dam. The air pressure is then raised in the instrument by means of a rubber bulb until the vein becomes obliterated as a result of the compression. During the compression there are two stages: (1) the obliteration of the vein, and (2) further blanching of the skin. The former has been selected as the end-point at which the pressure is read from the manometer. In a scries of patients, some of them with cardiac disease, the tabulated results obtained by this indirect method, as compared with those of the direct method, show a high degree of accuracy. The authors believe that with minor improvements in the instrument and technique the method can be adapted for general clinical use. -Archives of Internal Medicine, January, 1933. li, 1.

Radioscopic Study of the Beats of the Heart and the Pedicle.—Every complete study of the heart beats should, according to Emile Bordet, take into account (1) the direction of their transmission in relation to the systole of the pulse,

(2) their amplitude. The first point can be demonstrated well on the screen, the second imperfectly so; a third relates to the form which their course takes and is not a subject for radioscopy. Bordet made a radioscopic study of the pulsations of the heart and the pedicle from the top to the bottom on each margin, in both the normal and pathological states, with results in part as follows: In the normal state the arch of the aorta and the median arch at the level of the pulmonary artery present external pulsations at each systole, which are seen to be synchronous and of the same amplitude for the 2 vessels. In the pathologic state these beats may be exaggerated, diminished, or abolished. In the aortic insufficiency of endocarditis the beats of the aorta are often greatly exaggerated without those of the pulmonary artery being excessive, while the reverse is true in insufficiency of the pulmonary artery. In aortitis, when the walls have lost their elasticity, the beats are weak and sometimes lost. In the normal state the contour of the left ventricle is the seat of systolic movements of retreat from the base to the apex. To each contraction of the ventricle there corresponds a point directed toward the median line, followed by a point extruding in the opposite direction, of the same amplitude but slower to appear. The effect of the retreat of the shadow is to bring the shadow of the total image of the heart back within the diastolic contour. In the early stages of pathologic dilatation of the heart, the pulsations are exaggerated, becoming more rapid and stronger upon the least effort; in repose, they become attenuated, but are still excessive. In progressive insufficiency of the left heart, if an exaggerated amplitude is seen to diminish and fail, while the size of the cavities continues to increase, the prognosis is grave. It is not unusual to see extremely reduced pulsations in cases of mitral stenosis where the left ventricle is small. This is due not to a disturbance of contractility of the myocardium, but to the reduced work of the ventricle through diminution of the blood debit. The beats of the right border of the heart are more difficult to make out, owing to the organ's anatomic relations. In extreme auricular dilatation, however, it is possible to see the shadow of the heart animated with lateral displacements from left to right during systole, and from right to left during diastole. In tricuspid insufficiency the border corresponding to the right auricle is the seat of systolic expansions at each contraction of the right ventricle, owing to the reflux of blood which passively distends the walls of the auricle. Pulsations due to the presence of an aneurysm may also be observed on the right border of the heart, the image of which resembles that of auricular ectasia.-Archives des Maladies du Cœur, December, 1932,

LEGAL

REPORT OF THE COUNSEL

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York.

To the House of Delegates:

Gentlemen:

Your Counsel herewith submits his report for the activities of the Legal Department of the Medical Society of the State of New York for the period from March 1st, 1932, to and including January 31st, 1933. It will be noted that the report covers a period of eleven months. This is due to the fact that the House of Delegates meets this year in April and hence it was necessary to send this report to the Secreary's office for publication in the New York State Journal of Medicine not later than February 15th.

In his report last year your Counsel stated: "The past year has been an exceedingly busy one, both in court and in consultation. The appended figures state mere conclusions and give no adequate picture of the amount of work involved or the responsibility assumed." This statement applies with equal force to the present reporting period.

At the outset of this report your Counsel wishes to acknowledge his indebtednes for the assistance and cooperation rendered him by your distinguished President, Dr. Charles Gordon Heyd. Dr. Heyd has worked indefatigably in the interests of organized medicine in this State and much has been accomplished for the welfare of your Society and its individual members by his progressive leadership. Acknowledgment is also made of the advice and assistance of your everefficient Secretary, Dr. Daniel S. Dougherty. Dr. Dougherty's keen interest in every phase of the work of your Society has been an inspiration to his co-workers. In his position as Assistant Secretary Dr. Peter Irving has rendered conspicuous and faithful service. We greatly appreciate the labors of Dr. Frederic E. Sondern, who, as Chairman of the Insurance Committee, handled with painstaking care the many matters which have come before him and his Committee for consideration and decision.

During the reporting period your Society suffered a severe loss in the death of your Speaker, Dr. John A. Card. Dr. Card rendered invaluable service not only as Speaker of the House of Delegates, but also as Chairman of the Insurance Committee. In the latter capacity it was his custom to personally speak to the various district branches on the benefits of your group plan of insurance.

In making his report your Counsel adheres to the convenient category employed in previous years whereby his activities have been divided into three main divisions: (a) the actual handling of malpractice actions before courts and juries and in the appellate tribunals; (b) counsel work with officers, Committees and individual members of the Society; and (c) legislative advice and activities.

Litigation

It is customary to call to the attention of your members in these annual reports the ever-present possibility of a malpractice action and the hazard presented by such lawsuit. We again wish to repeat and emphasize that no active practitioner can consider himself free from the possibility of legal action being taken against him for alleged malpractice. The physician should also bear in mind that under our law the facts of these cases are considered and passed upon by twelve lay jurors. While passion, prejudice and bias should not enter into the verdict of a jury, every lawyer who practices in our courts can testify that these elements do affect and in fact are responsible for the fantastic results sometimes arrived at by juries.

In the field of litigation it is pleasing for your Counsel to report the splendid progress made and the results obtained by his associate, Mr. William F. Martin. Mr. Martin had served under your Counsel's predecessor, Mr. Lloyd Paul Stryker, and from the outset demonstrated that he possessed those qualities which make for success in the field of advocacy. Mr. Martin's ability in the trial of these cases has been the subject of favorable comment not only from individual members of the Society, but also from the judges before whom he has appeared in the various courts of the State.

Your Counsel also wishes to record the splendid work done by his associate, Mr. Thomas H. Clearwater, the Attorney for the Society. Acknowledgment should also be made of the fine spirit of cooperation and loyalty shown by your Counsel's entire office staff.

From the accompanying Table I it will be noted that the same number of cases, 292, were instituted in this eleven month period as in the preceding year. We disposed of 188 cases as against 227 during the preceding year. This figure does not include, however, 13 cases tried during the

present reporting period which resulted in mistrials. Also the figures do not include a large number of claims in which we were successful in persuading the claimants or their attorneys not to bring suit. A large number of claims still remain outstanding in which suit may ultimately be brought.

Of the 188 cases disposed of during the reporting period, 28 have been settled, in 153 cither judgments for the defendant have been secured after trial or they have been disposed of through dismissal, discontinuance or abatement. In 7 cases only was judgment rendered in favor of the plaintiff, and 3 of these cases are at pres-

ent pending on appeal.

It will be noted from Table I that there are now pending 747 cases. In connection with this figure your Counsel wishes to state that a complete inventory taken by his office of every pending matter discloses that of the 747 cases pending on January 31st, 1933, as listed in Table I, there are actually pending at this time 568 main eases and 179 eompanion actions (actions for loss of serv-

office at the date of this report 568 litigated matters.

We have already referred to the hazard involved in the trial of a malpractice action. Fortunately, the members of your Society have an opportunity to adequately protect themselves through the benefits afforded by your group plan of insurance. This plan has now been in operation for over a decade and its successful operation has been the subject of warm approbation from the members of your Society.

Your Insurance Committee, under the able leadership of Dr. Frederic E. Sondern, has rendered during the recording period a very real service to the members of your Society. This Committee has met on a number of occasions and has given painstaking care and consideration to the matters which have come before it for decision.

Table 11 hereto appended gives a comparison of the number of members insured in 1930, 1931, 1932 and 1933 and the number of members in the County Societies, and the percentage of insured members in the County Societies and in the entire

yearly period; while 7,925 members are now insured, representing an increase of 226 insured members over the previous period. The percentage of insured members is now 59%, or an increase of 1% over the previous year.

Counsel Work

During the period of this report, your Counsel has prepared for publication in the Society's Journal articles in the nature of editorial comment. These editorials have included the following:

Rights and Liabilities in Connection with Bodies of Deceased Persons.

Challenge to the Bar.

Group Plan of Insurance.

Legal Liability of Employer for the Acts of a

Physician Employee.

Review of Some Interesting x-ray Burn Cases. Private Hospitals—Legal Liability for Acts of Nurse.

Negligence Actions-Mention of Insurance

Ground for Mistrial.

Libel — Defamatory Statements Concerning Deceased Persons.

Dr. John A. Card.

Judicial Interpretation of the Practice of Medicine.

Insurance-Death by Suicide.

Evidence—Improper Questions as to Physician's Wealth.

Malpractice—Legal Standard in Civil Action Against Unlawful Practitioners.

Actions for Death by Wrongful Act—Right of Adverse Party to Participate in Autopsy.

Privileged Communications — An Interesting Case.

Liability for Experimental Diagnosis and Treatment.

Privileged Communications.

Scottsboro Case

Druggist's Liability in Filling Physician's Prescription.

Autopsy—Hospital Held Not Responsible for Autopsy Performed by Medical Examiner.

Necessity for Medical Testimony in Malpractice Actions.

Your Counsel has also digested and there have been published in the Journal reports upon malpractice actions which it has been felt were of special interest to the profession. The case reports published during the previous year are as follows:

Malpractice Claimed in Treating Industrial Accident.

Claimed Negligence in Treatment of Sinus Trouble.

Broken Needle.

Alleged Negligence in Use of Tourniquet. Counterclaim of Malpractice Based on Trea

Counterclaim of Malpractice Based on Treatment of Ear.

Alleged Negligence in Treatment of Colles' Fracture.

Counterclaim, Claiming Failure to Diagnose liness.

Claimed Negligence with Respect to Breaking of Needle.

Treatment of Colles' Fracture.

Lung Abscess Following Tonsillectomy.
Application of Iodine Petrogin to Throat.

Application of found Ferrogin to Timoat.

Alleged Negligent Treatment of Hemorrhoids.

Loss of Teeth During Tonsillectomy. Fracture of Tibia and Fibula.

Removal of Appendix During Operation for Hernia.

Treatment of Peritonsillar Abscess.

Claimed Failure to Remove Gallstones.

Alleged Negligent Treatment of Burns.
Claimed Failure to Properly Treat Mental

Case.
Claim of Negligence in Administering Anti-

toxin.
Treatment of a Fractured Leg.

Death Following Tonsilectomy.

Claimed Negligence by Family Doctor in

Treating Children of Defendant.
Alleged Failure to Treat Child's Injury Prop-

erly. Sun-Ray Burn.

Claim of Negligence in Cystoscopy Examina-

Treatment of Laceration of Eyelid—Loss of Eye.

Needle-Breaking During Administration of Toxin-Antitoxin.

Injuries Received by Heat Lamp Bursting. Claimed Negligent Prenatal Care and Delivery.

Physical Examination to Test Intoxication.

Abdominal Operation—Malpraetice Cas Barred by Judgment for Doctor's Bill.

Incontinence of Urine Following Operation.

In his contacts with the members of your Society your Counsel is pleased to find that these editorials and ease reports are read with approval and interest by the members of your Society.

In addition to his other duties, your Counsel frequently receives requests for opinions on various subjects. It should be remembered that the Executive Committee of your Society has ruled that requests for legal opinion, whether coming from individual members of your Society or from component County Societies, must in the first instance be referred to that body for action. If the Executive Committee deems the inquiry a proper one for opinion by Legal Counsel, it refers the same back to him for reply. Some of the matters upon which advice has been thus rendered by your Counsel are the following:

Communication inquiring, where a patient showing no pathology and well within the child-bearing period requests that she be sterilized:

- (a) What is the criminal liability of a physician who accedes to this request?
- (b) What is the civil liability of such physician?

Inquiry where a surgeon agrees on a stated fee for an operation and thereafter engages an assistant, as to whether the assistant physician can collect for services from the patient or from the surgeon.

Inquiry as to whether a malpractice action can be instituted after the expiration of two years from the date of last treatment; and also as to the advisability of bringing suit for professional services where a counterclaim of claimed improper treatment is likely.

Communication requesting legal decisions and

opinion in regard to chiropractors:

(a) What standing has a chiropractor for the alleviation or cure of human abnormalities in New York State?

(b) Whether oral or written, can a chiropractor assume the resignation as "Doctor"?

(c) Can a chiropractor collect a bill for services rendered for the alleviation or cure of human abnormalities?

Inquiry as to whether the employer of a doctor is responsible for the physician's treatment of employees, or whether the physician alone is responsible.

Communication requesting the following information with reference to the performance of autopsies:

(a) Is a case admitted to a hospital public ward and dying within twenty-four hours a coronor's case whether or not a diagnosis is made?

(b) Is it permissible for the pathologist of such hospital to perform an autopsy in such case, if he has permission of the

next-of-kin and the coroner?

(c) In general, in what order of precedence do relatives have authority over a body?

(d) Where the family has agreed to the autopsy, is it necessary that the very next-of-kin give permission, or may a more distant relative give such?

(e) Where the patient has no blood relatives known to the hospital, may a close friend who is perhaps the only one interested give permission for an autopsy?

(f) Is it necessary to have written permission?

Inquiry as to whether a physician may legally sign a death certificate if either of his parents die while under his care before another physician can be called.

Inquiry as to whether the group plan policy covers a physician:

- (a) Where a nurse assistant gives treatment directed by a physician to a patient personally seen by him;
- (b) Where the physician, taking a vacation, requests the nurse assistant to give treatment during his absence.

Inquiry as to whether the attending obstetrician or the actual attendant to the mother at the birth, who may be an interne at the hospital, should sign the birth certificate.

Communication inquiring, where a physician who had some time previously examined or treated a patient, has the same person referred to him by an insurance carrier for examination:

- (a) Is it ethical for the physician to make such second examination?
- (b) If so, is it permissible for him to include in his report such knowledge as he gained from his first examination, which information would not have been ascertainable from the second examination alone?
- (c) Should he be called as a witness in court, which portion of his information may he divulge?
- (d) If he refers the patient to another doctor for said second examination, may he divulge to the second doctor or the insurance carrier such knowledge as he gained in his first examination?
- (e) Should he be called as a witness in court, may he divulge the information gained from his first examination, where he has referred the patient to another doctor for the second examination?
- (f) Does the submission by the patient to the second examination constitute a waiver of confidential communications?

Communication requesting opinion as to the legality and adequacy of a consent to operation used at a charitable hospital, and suggested revision.

Communication with regard to advertising by licensed lay physiotherapists, inquiring:

- (a) Whether such advertisements may contain other matter than the name, address, telephone number and title of the licensed physiotherapist;
- (b) Whether such lay physiotherapists are subject to the same ethical stringency in regard to advertising as physicians.

Communication regarding a patient who has been treated in the free ward of a municipal hospital, inquiring:

- (a) Can such patient recover for alleged malpractice against the physician?
- (b) Can such patient recover against the city?

(e) Does the fact that it was a charity case absolve the physician from liability?

Communication from an ophthalmologist inquiring:

- (a) Has an ophthalmologist or physician the legal right to recommend or criticize an optician?
- (b) To what extent may he criticize the optician's mountings and quality of workmanship?
- (e) What care should he exercise in so recommending or criticizing, in order to avoid suit for libel or slander?

The foregoing list does not include a number of communications received from physicians requesting reprints and further details in regard to the published editorials.

Your Counsel has also rendered his legal opinion and given advice to various County Societies in regard to the following:

Revised constitution and by-laws of the Medical Society of the County of St. Lawrence.

Where a County Society at a regular meeting approves the reimbursement of counsel and other fees to a member of said Society, who without knowledge of the Society or its executive office has secured the conviction of an unlicensed practitioner of medicine.

- (a) Has the Society the legal right to pay such moneys?
- (b) Is the Comitia Minora, which has the power to direct the expenditure of funds appropriated at any meeting, authorized to nullify such appropriation?
- (e) By paying such moneys, does the Society make itself a party to the original transaction and liable to countersuit?

Resolution by the Executive Committee that the Legal Counsel and the President render to the Medical Society of the County of New York, the opinion expressed by said Executive Committee in regard to the reduction of the State Society's dues and the acceptance of the State Society's assessments in partial payments.

Your Counsel has been in conference and con-

sultation with the members of the Committee on Insurance with respect to the various matters which have been referred to them for action. This Committee has revised and clarified the resolutions of the State Society relating to malpractice defense.

Your Counsel has also attended several meetings of the Committee on Medical Economics, and has also conferred on a number of occasions with Dr. Charles H. Goodrich, Chairman of the said Committee. In this connection your Counsel has prepared proposed amendments to the General Municipal Law and the Public Welfare Law in relation to the certification of the indigent in connection with care and treatment at public hospitals. Also your Counsel has prepared proposed amendments to the Lien Law so as to provide for a lien by physicians for treatment rendered to persons injured in motor vehicle accidents. Your Counsel has also examined and discussed with Dr. Goodrich a large number of proposed amendments to the Workmen's Compensation Law.

Your Counsel has also acted as advisor to the Sub-Committees which have been appointed by the President to study and consider the various reports of the standing Committees.

Legislative Advice and Activities

As this report is being written, the Legislature has only been in session for about a month. Your Counsel has examined a number of proposed bills affecting the medical profession and has given advice with respect to them. He has also drafted several bills for introduction to the Legislature at this session.

Conclusion

At the conclusion of this report your Counsel desires to express his thanks to the large number of physicians who have given so graciously of their time and talents in cooperating with your Legal Counsel in the defense of malpractice actions. This assistance is in no small measure responsible for the results shown by this report.

Respectfully submitted,

LORENZ J. BROSNAN, Counsel. February 1st, 1933.

THE ANNUAL MEETING

FEATURES AND PROGRAMS OF THE ANNUAL MEETING

The one hundred and twenty-seventh annual meeting of the Medical Society of the State of New York will be held on Monday, Tuesday and Wednesday, April 3-5, 1933, in the WaldorfAstoria Hotel, New York City. The major features of the meeting will be those established by the precedents and experiences of past years, with some new ones added.

THE ANNUAL REPORTS

The Annual Meeting may properly be said to begin with the publication of the Annual Reports of the officers and committees of the Medical Society of the State of New York to the House of Delegates, for these reports are the basis of the greater part of the discussions and actions by the House. These reports are printed in this issue of the Journal, taking the place of its Scientific Department. They are referred to Reference Committees appointed by the Speaker of the House of Delegates for the purpose of digesting their facts and judging the recommendations; but they are equally available to every member of the Society. The early publication of the reports has expedited the business of the House of Delegates, and eliminated controversies and misunderstandings regarding the policies of the officers and committees.

THE HOUSE OF DELEGATES

The business of the Society will be transacted by the House of Delegates which will hold its meetings on Monday, in the afternoon and evening, with a social dinner between the sessions. The program will be as follows:

2:00 P.M.—Calling the House to order.

Report of the Retiring President, Dr. Chas. Gordon Heyd, New York.

Inaugural address of Incoming President, Dr. Thomas H. Flaherty, Syracuse.

6:30 P.M.—Dinner of Delegates.

The Dinner of the House of Delegates is open to any member of the Society. Tickets may be obtained by sending check to the Secretary, care of the Society, 2 East 103rd Street, New York City, for \$2.50 per ticket.

7:30 to 8:45—Addresses:

1. Compulsory Health Insurance and the Panel System, Dr. Emil Koffler, New York. Illustrated with lantern slides.

- 2. The Participation of the Physician in Public Health Work, Dr. Henry F. Vaughan, Health Commissioner, Detroit, Michigan. Illustrated with lantern slides.
- 3. The participation of the Physician in Rural Health Work, Dr. Stuart Pritchard, Grand Rapids, Mich.
- 4. Introduction of Dr. George McCleary, of London, England. Medical Officer of the Ministry of Health.

8:45 P.M.—Calling of the House of Delegates to Order.

Presentation of the Report of the Special Committee on the Cost of Medical Care. Dr. Arthur W. Booth, Elmira, N. Y., Chairman.

The report of this committee will be considered in executive session to which only members of the House of Delegates will be admitted.

admitted.

The House of Delegates will complete its labors on Tuesday morning, ending with the election of officers of the State Society.

THE ANNUAL MEETING

The Annual Meeting of the Medical Society of the State of New York will be held in connection with the Banquet of the Society in the Grand Ball Room of the Waldorf-Astoria Hotel at seven p. m., on Tuesday, April 4, 1933. Program is as follows:

- 1. Invocation.
- 2. Calling the meeting to order, Dr. Charles Gordon Heyd.
 - 3. Reading of minutes.
- 4. Introduction of Dr. Samuel J. Kapetzky, Chairman of the Committee on Arrangements.
 - 5. Introduction of Dr. Terry M. Townsend,

President of the Medical Society of the County of New York, who will act as toastmaster.

- 6. Introduction of the Presidents of the Medical Societies of the Counties of New York.
- 7. Introduction of Dr. Edward H. Cary, President of the American Medical Association.
- 8. Introduction of Dr. Olin West, Secretary of the American Medical Association.
- 9. Address of the incoming President of the Medical Society of the State of New York, Dr. Frederick H. Flaherty.
- 10. Address, "Medicine of the Future," Dr. Howard W. Haggard, New Haven, Connecticut.

11. Address, "The Medical Society of the State of New York, Our Responsibility and Our Obligation," Dr. Chas. Gordon Heyd.

Teckets for the Annual Banquet may be obtained by sending check to the Secretary of the Society, 2 East 103rd Street, New York City. Price of tickets, \$5.00. If listed seating is desired it is necessary that the Secretary be informed not later than March 25, after that date the seating places will be unassigned.

SCIENTIFIC PROGRAM

A series of scientific meetings at which professional papers will be presented will be the central feature of the annual meeting. General sessions will be held on the afternoons of Tuesday and Wednesday, while meetings of the eight Scientific Sections will be held on Tuesday and Wednesday mornings, and sessions on Physical Therapy and Roentgenology on Wednesday morning.

The programs of the general session, and the scientific questions, are published in this Journal, beginning on page 319.

The papers and addresses will be published in the New York State Journal or Medicine. The following notice will therefore be printed on the program of each section:

"Essayists will please leave the original copies of their papers with the Secretary of the Section when they finish reading them. All papers read before the Society by its members shall become the property of the Society. Discussers must type their remarks and hand them to the same officer if they wish to have them published in the Journal."

The Committee on Scientific Work, which has made up the program, is as follows:

Arthur J. Bedell, M.D., Albany, Chairman; Edward C. Reifenstein, M.D., Syracuse; Edward R. Cunniffe, M.D., Bronx, New York City;

Edward C. Hughes, M.D., Syracuse; Brewster C. Doust, M.D., Syracuse; David F. Gillette, M.D., Syracuse; Daniel R. Reilly, M.D., Cortland; Henry W. Williams, M.D., Rochester; Paul E. Bechet, M.D., New York; Frederic E. Sondern, M.D., New York City.

THE SCIENTIFIC EXHIBIT

A scientific exhibit, arranged under the leadership of Dr. Frederic E. Sondern, will be open during the whole time of the Annual Meeting, in a large room which will be easy of access from the Registration Booth and the main assembly hall. The program of exhibitors is printed on page 325 of this Journal. This scientific exhibit will be conducted along the lines of those of previous years, but it will be more extensive and comprehensive than ever before.

CLINIC DAY

Monday, April 3, 1933, will be "Clinic Day," when an extensive series of Clinical Demonstrations and Surgical Operations will be made available in many of the leading hospitals of New York City.

The full program of the clinies appears in this Journal, beginning on page 326. A daily list of clinies and operations in all the hospitals of Greater New York will be on file at the Information Bureau of the Annual Meeting.

OPEN MEETING

The 127th Annual Meeting of the Medical Society of the State of New York will terminate on Wednesday, April 5, 1933. The final Session at 8.30 p.m. will consist of a meeting open to the public wherein topics on general medical information will be discussed by distinguished clinicians. The program will be as follows, Dr. Chas. Gordon Heyd, Chairman:

- 1. The Community and the Physician, Olin West, M.D., Chicago, Ill., Secretary and General Manager American Medical Association.
- 2. What the Community Should Know about Arthritis, Lewellys F. Barker, M.D., Baltimore, Md.

- 3. What the Community Should Know About Goiter, Frank H. Lahey, M.D., Boston, Mass.
- 4. What the Community Should Know About Appendicitis, Dean DeWitt Lewis, M.D., Baltimore, Md.
- 5. What the Community Should Know About Diabetes, Elliott P. Joslin, M.D., Boston, Mass.
- What the Community Should know About Tuberculosis, Linsly R. Williams, M.D., New York City.
- 7. The Health of the State, Thomas Parran, Jr., M.D., Albany, N. Y., Commissioner, State Department of Health.
- Admission will be by tickets. These may be obtained, gratis, from the Secretary of the Society, 2 East 103rd Street, New York City.

THE TECHNICAL EXHIBIT

There will be an extensive technical exhibit at which over fifty manufacturers and dealers in medical supplies and hospital equipment will demonstrate their wares and dispense samples and literature. This exhibit will be the most extensive that the State Medical Society has shown for years. A description of the individual booths is printed in this Journal, beginning on page 332.

The greater number of the exhibitors are advertisers in the Journal, and have a kindly feeling toward the State Society. The members can show a reciprocal feeling by calling at the booths, and taking a personal interest in the wares and demonstrations, forming the personal acquaintance of the exhibitors, and registering for samples and literature.

REGISTRATION AND INFORMATION

A Registration Table and Information Bureau will be maintained in a conspicuous location near the elevators and the main entrance to the meeting rooms and exhibits. Attendants will be constantly on hand to direct the members and to give information on all questions relating to the An-

nual Meeting. The attendants will also give out the official badges for the members of the House of Delegates, and issue tickets for the Delegates' Dinner on Monday, the Banquet and Dance on Tuesday, and the Public Meeting to be held on Wednesday evening.

PRESS SERVICE

A new feature of the Annual Meeting will be an organized provision for informing the public of the proceedings by means of the newspapers and the radio. The details of the methods of publicity will be in charge of a special committee consisting of:

Dr. Frederic E. Sondern, Chairman;

Dr. George W. Kosmak;

Dr. Clarence G. Bandler;

Dr. John C. A. Gerster;

Dr. Iogo Galdston;

Dr. Samuel J. Kopetzky;

Dr. Charles Gordon Heyd.

Special Committee on Radio Broadcasting;

Dr. Iogo Galdston;

Mrs. R. S. Hirschman (Courtesy of the New York Tuberculosis and Public Health Association).

Special Press Representative:

Mr. Dwight Anderson.

The committee has the active cooperation of the Medical Information Bureau of the Medical Society of the County of New York and the New York Academy of Medicine.

The committee plans to maintain a staff in a room set aside for the purpose where reporters will be received and all information given out. Press releases will be prepared and issued, and every facility will be provided to supply the representatives of the Press with all proper information.

All publicity of the Annual Meeting must be cleared through the Special Committee on Publicity. Members desiring consideration for their papers will please submit copy of the same at least five days before presentation, to the Chairman of this Committee, Dr. Frederic E. Sondern.

The Committee on Press Service also plans to arrange programs with radio companies so that prominent physicians shall broadcast talks on medical subjects several times during the meeting.

Since medical societies throughout the nation are actively promoting the education of the people regarding the value of medical service, the work of the Committee on Press Service will be of essential importance to every physician in New York State.

COMMITTEE ON ARRANGEMENTS

While practically all the officers and members of committees have been concerned with the plans and programs for the many features of the Annual Meeting, yet the coordination of the details and the smooth running of all phases of the meeting is insured by the Standing Committee on Arrangements of which Dr. Samuel J. Kopetzky, New York, is Chairman.

Every one from the President of the Society to

the clerical force has put forth every effort to make this Annual Meeting an outstanding success. The plans are completed to their smallest detail, and the Hotel Waldorf-Astoria assures plenty of room and comfort.

The acceptance of the plans by the members will be the final act that will make this Annual Meeting the best in the history of the Medical Society of the State of New York.

SCIENTIFIC PROGRAM

All the meetings will be held in the Waldorf-Astoria Hotel.

THE GENERAL SESSIONS

Tuesday, April 4th, at 2:00 P.M.

ADDRESS

Address by the President of the American Medical Association, Edward H. Cary, M.D., Dallas, Texas. (Invited Guest.)

SYMPOSIUM ON DENTAL CONDITIONS AS THEY AFFECT GENERAL HEALTH

1. "Dental Service in Diabetes." Harold A. Kent, D.D.S., Boston, Mass. (Invited Guest.)

Discussion opened by Henry R. Geyelin, M.D., New York City.

2. "Nutritional Control of Dental Caries," Ewing C. MeBeath, M.D., D.D.S., New York City. (Invited Guest.)

Discussion opened by Royal S. Haynes, M.D., New York City, Charles F. Bodecker, D.D.S., New York City. (Invited Guest.)

3. "Pyorrhea and Its Relation to Oral and General Health," Arthur H. Merritt, D.D.S., New York City. (Invited Guest.)

Discussion opened by William R. Williams, M.D., New York City, Isidor Hirschfeld, D.D.S.,

New York City. (Invited Guest.)

4. "Oral Conditions as Aids in Diagnosis of Systemic Diseases," Lester R. Calin, D.D.S., New York City. (Invited Guest.)

Discussion opened by Harlow Brooks, M.D., New York City.

Wednesday, April 5th, at 2:00 P.M. SYMPOSIUM ON SOME DISORDERS OF LIVER FUNCTION

1. "Observations Upon the Deposition of Liver Fat in Normal and Diabetic Animals," Charles H.

Best, M.D., Toronto, Canada. (Invited Guest.)
2. "The Relation of Biliary Dysfunction to
Lithiasis," Lester R. Whitaker, M.D., Boston, Mass. (Invited Guest.)

- 3. "Pathology of Jaundice," Paul Klemperer, M.D., New York City.
- 4. "The Significance of Liver Function from the Surgeon's Standpoint," Chas. Gordon Heyd, M.D., New York City.

THE SECTIONS

Essayists will please leave the original copies of their papers with the Secretary of the Section when they finish reading them. All papers read before the Society by its members shall become the property of the Society.

Discussers must type their remarks and hand them to the same Officer if they wish to have them published in the Journal.

SECTION ON MEDICINE

Chairman Edward C. Reifenstein, M.D., Syracuse Secretary.......Alfred M. Wedd, M.D., Clifton Springs

Tucsday, April 4th, at 10:00 A.M.

1. "A General Discussion of Oxygen Therapy," Lantern Slide Demonstration, Alvan L Barach, M.D., New York City

Discussion opened by John J. Buettner, M.D., Syracuse, and Joseph R. Wiseman, M.D., Syra-ČUEO.

2. "Cavities of the Lung in Pulmonary Tuberculosis—Their Management," Lantern Slide Demonstration, Edgar Mayer, M.D., Saranac Lake.

Discussion opened by Pol N. Coryllos, M.D.,

New York City.

3. "The Treatment of Common Forms of Dropsy," Nellis B. Foster, M.D., New York City.

Discussion opened by Nelson G. Russell, M.D., Buffalo.

4. "Calcium Metabolism in Arthritis," Edward F. Hartung, M.D., New York City.

Discussion opened by John S. Davis, Jr., M.D., New York City.

5. "Clinical Observations on Achlorhydric Anemia," Nathan Rosenthal, M.D., New York City.

Discussion opened by I. Harris Levy, M.D., Syracuse.

Wednesday, April 5th, at 9:00 A.M.

SYMPOSIUM ON VASCULAR DISEASE

1. "Hypertension and Nephritis," Maynard E. Holmes, M.D., Syracuse.

Discussion opened by Herman O. Mosenthal, M.D., New York City.

2. "Some Practical Problems in the Handling of Peripheral Arterial Disease," Lantern Slide Demonstration, W. J. Merle Scott, M.D., Rochester.

Discussion opened by Leo Buerger, M.D., New York City.

- 3. "Coronary Disease and Its Relation to the Increase of Cardiac Morbidity," Louis F. Bishop, M.D., New York City, Louis F. Bishop, Jr., M.D., New York City.
- 4. "Some Points in the Diagnosis and Prognosis of Coronary Thrombosis," Robert H. Halsey, M.D., New York City.

Discussion opened by Emanuel Libman, M.D., New York City, Harold E. B. Pardee, M.D., New York City, John Wyckoff, M.D., New York City.

SECTION ON SURGERY

Tuesday, April 4th, at 10:00 A.M.

- 1. "Blood Changes in Intestinal Obstruction," Dana W. Atchley, M.D., New York City.
- 2. "Etiology of Intestinal Obstructions," Joshua E. Sweet, M.D., New York City.
- 3. "Treatment of Intestinal Obstruction," John J. Morton, Jr., M.D., Rochester.
- 4. "The Diagnosis and Management of Carcinoma of the Colon and Rectum," Frank H. Lahey, M.D., Boston, Mass. (Invited Guest.)

Wednesday, April 5th, at 9:00 A.M.

- 1. "Surgery of the Patient with Diabetes Mellitus." Beverly C. Smith, M.D., New York City.
- 2. "Surgery of the Patient Complicated with Pulmonary Disease," Frank B. Berry, M.D., New York City.
- 3. "Surgery of the Patient Complicated with Thyroid Disease," Roderick V. Grace, M.D., New York City.
- 4. "Discussion of the Factors for Safety in Surgery of Infants," Edward J. Donovan, M.D., New York City.

SECTION ON OBSTETRICS AND GYNECOLOGY

Tuesday, April 4th, at 10:00 A.M.

1. "A Study of Maternal Mortality in New York State." George W. Kosmak, M.D., New York City.

SYMPOSIUM ON 'TOXEMIAS OF PREGNANCY AND SOME OF THEIR COMPLICATIONS"

2 "Nephritis and Pregnancy" Henricus J Stander, M.D., New York City

Discussion opened by Eliot Bishop, MD, Brooklyn

3 "Abruptio Placenta," Henry W Schoeneck, M D, Syracuse

Discussion opened by George L Brodhead,

M.D. New York City
4 "Treatment of Toxemins of Pregnancy and

Their Complications," Benjamin P Watson, M D, New York City

Discussion opened by Karl M Wilson, MD, Rochester

5 'Methods of Induction of Labor in Respect to the Toxemias," Francis C Goldsborough, M.D. Buffalo

Discussion opened by Albert H Aldridge, M D. New York City

Wednesday, April 5th, at 9 00 A.M

SYMPOSIUM ON GYNECOLOGICAL NEOPLASMS

1 ' Freatment of Carcinoma of the Cervix," William P Healy, M.D., New York City

Discussion opened by Walter T Dannreuther, M D, New York City

2 "Treatment of Carcinoma of the Fundus," Thomas P Farmer M.D. Syracuse

Discussion opened by James E. King, M.D., Buffalo

3 "Treatment of Uterine Myomata," Robert A Kimbrough, Jr, MD, Philadelphia, Pa (In vited Guest)

Discussion opened by Howard C Taylor, M D New York City

4 "Mainmary Carcinoma" Frank E Adaii, MD, New York City

5 'Ovarian Neoplasins," Howard C Taylor Ir MD New York City

SECTION ON NEUROLOGY AND PSYCHIATRY

Chairman Secretars Henry W Williams M D Rochester

Tuesday, April 4th, at 10 00 A M

1 'The Morbid Process of Migraine," Foster Kennedy, MD New York City

Discussion opened by Henry A Riley MD, New York City

2 "Neurological and Mental Symptoms in Pernicious Anamin F Livingston Hunt M.D. New York City Discussion opened by Paul H Garvey, MD, Rochester

3 "Colloidal Chemistry and Psychiatry," H Beckett Lang, M D, Marcy

4 "Anxiety as a Medical Problem," Sandor Lorand, MD, New York City

Discussion opened by Abraham A Brill M D New York City

Wednesday, April 5th, at 9 00 A M

1 'Congenital Word Deafness," Samuel T Orton, MD, New York City

Discussion opened by Frederick Tilney, M D, New York City

2 "Disorders of Muscle Tone and Their Lo calizing Significance," Walter Freeman, MD, Washington, DC (Invited Guest)

Discussion opened by James R Hunt, MD,

New York City

3 'Surgical Relief of Intractable Pain," Francis C Grant M D Philadelphia Pa (Invited Guest)

Discussion opened by Leo M Davidoff, MD, New York City

4 "Radiotherapy in Disseminated Spinal Arachnoiditis,' Herman Selinsky, MD, New York City

Discussion opened by Charles W Schwartz, M D , New York City $\,$

5 "Cramal Neurnts," Samuel Brock, M.D. New York City, S. Bernard Wortts, M.D., New York City

Discussion opened by Israel S Wechsler, M D New York City

SECTION ON PEDIATRICS

Chairman	E	Brewster	C.	Doust,	M.D.	., Syra	cuse
Vice-Chairman	Adolph G.	DeSand	tis,	M.D.,	New	York	City
Secretary	Geor	ge C. S	inco	rbcaux	, M.I)., Au	burn

Tuesday, April 4th, at 10:00 A.M.

1. "The Pitressin Test for Epilepsy," A. Wilmot Jacobsen, M.D., Buffalo.

Discussion opened by Noble R. Chambers,

M.D., Syracuse.

2. "The Relation of Infections to Nutrition in Infants and Small Children," Marshall C. Pease, M.D., New York City.

Discussion opened by Marvin F. Jones, M.D., New York City, Frank vander Bogert, M.D.,

Schenectady.

3. "The Common Skin Conditions in Children," Howard Fox, M.D., New York City.

Discussion opened by Albert R. McFarland, M.D., Rochester, Frank C. Combes, M.D., New York City.

4. "Abdominal Pain in Children," Edward S. Rimer, M.D., New York City.

Discussion opened by Edward J. Wynkoop, M.D., Syracuse.

Wednesday, April 5th, at 9:00 A.M.

1. "Preventing the Loss of Weight in the New Born," I. Newton Kugelmass, M.D., New York City.

Discussion opened by Norman C. Bender, M.D., Buffalo.

2. "The Exploitation of the Vitamines," Samuel W. Clausen, M.D., Rochester.

Discussion opened by Adolph G. DeSauctis, M.D., New York City, T. Wood Clarke, M.D., Utica.

3. "Recent Dietary Studies of Practical Interest to the Physician," Frederick F. Tisdall, M.D., Toronto, Canada. (Invited Guest.)

Discussion opened by William J. Orr, M.D., Buffalo, Paul W. Beaven, M.D., Rochester.

4. "A Clinical Study of Enuresis," Meredith

F. Campbell. M.D., New York City.

Discussion opened by John D. Lyttle, M.D., New York City, Charles H. Smith, M.D., New York City.

5. "Cardiospasm and Other Obstructions of the Upper Gastro-intestinal Tract in the New Born." Lantern Slide Demonstration, John Aikman, M.D., Rochester.

Discussion opened by E. Forrest Merrill, M.D., New York City, George M. Retan, M.D., Syracuse.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Chairman	Paul	E.	Bechet,	M.D.,	New	Yorl	i City
Secretary	F	Ierb	ert H.	Baucku	s. M.	D., B	uffalo

Tuesday, April 4th, at 10:00 A.M.

SYMPOSIUM ON DERMATOTHERAPY

- 1. "Personal Impressions in the Treatment of a Few of the Commoner Inveterate Types of Skin Disease," Fred Wise, M.D., New York City.
- 2. "Unfiltered X-rays and the Ten Milligram Flat Radium Element Applicator in Dermatology," A Résumé of Personal Experience and Opinion, George M. MacKee, M.D., New York City.
 - 3. "Some Personal Impressions of Present
- Day Syphilotherapy," John H. Stokes, M.D., Philadelphia, Pa. (Invited Guest.)
- 4. "Personal Experience in the Prophylaxis and Treatment of Ringworm of the Hands and Feet." Earl D. Osborne, M.D., Buffalo, Edwin D. Putnam, M.D., Buffalo, Raymond J. Rickloff, M.D., Buffalo.

Discussion opened by Edward R. Maloney, M.D., New York City, Charles M. Williams, M.D., New York City.

Wednesday, April 5th, at 9:00 A M.

I. "Lymphogranuloma Inguinale of the Tongue and Cervical Glands." Report of a Case, David Bloom, M D, New York City.

Discussion opened by Louis B Mount, M.D.,

2 "Photography in Dermatology," A New Method, Kenneth M Davenport, MD, Roch-

Discussion opened by John H Hunt, MD,

Elmira.

3 "Pemphigus," Jerome Kingsbury, M.D., New York City, A Benson Cannon, M.D., New York City.

Discussion opened by Binford Throne, M.D. Brooklyn

4 "Biopsy as an Aid to Diagnosis," Sigmund Pollitzer, M.D., New York City.

Discussion opened by J Frank Fraser, MD, New York City.

5. "Acrodynia," Two Cases in One Family, Lopo de Mello, MD, Syracuse, James R Wilson, M.D. Syracuse

Discussion opened by Albert M Crance, M D.

Geneva

SECTION ON OPHTHALMOLOGY AND OTO-LARYNGOLOGY

Chairman

Secretary ...

David F Gillette, M.D., Syracuse Frank M Sulzman, M D, Troy

Tuesday, April 4th, at 10 00 A M. SYMPOSIUM ON CHRONIC SIMPLE GLAUCOMA

1 "Diagnosis," Searle B Marlow, MD. Syracuse

Discussion opened by Arthur J. Bedell, M.D., Albany, John N Evans, M D, Brooklyn, Manuel U. Troncoso, M.D. New York City

Narcotic Drug Addiction, A. O. Gettler, M.D.,

Office Chief Medical Examiner.

Subject to be announced. Harrison S. Martland,

M.D., Newark City Hospital.

Influence of Food on Teeth and Jaws of Eskimo, L. M. Waugh, D.DS., Columbia University School of Dental and Oral Surgery.

Special Caries Research, H. J. Leonard, D.D.S., Columbia University School of Dental and Oral

Surgery.

Clinical Oral Pathology, Theodor Blum, M.D., New York Institute of Clinical Oral Pathology.

X-ray Studies, I. Seth Hirsch, M.D., Beth Israel Hospital.

Laboratory Aids in Diagnosis, Division of Laboratories and Research, N. Y. State Departof Health.

Tumors of Mouth, Charles G. Darlington, M.D., N. Y. University Dental College.

Photomicrographs of Uterine Tumors, Frederic E. Sondern, M.D.

THE CLINIC DAY

Monday, April 3rd, 1933

Special arrangements have been made by certain hospitals, medical schools, and dental schools of the City to welcome members of the Society at operative clinics, ward rounds, lectures and demonstrations both morning and afternoon. Advance information of these opportunities follows, but members should secure up to the minute "Detail Sheets" at the time of registration at the reg-

istration booth of the Society in the Hotel Waldorf-Astoria. These sheets show the nature of each operation, time and surgeon as supplied by the local Clinical Information Bureau.

In addition regular operative clinics will occur on Monday, in all of the other hospitals in Manhattan, Bronx, Kings, Queens and Richmond, details of which also show on the Bureau sheets.

BELLEVUE HOSPITAL

First Avenue and 26th Street

Monday Morning

8:30-12:30-K5 Operating Rm. 1st Div. Operative Clinic, John A. McCreery, M.D., and Staff.

9-12:30—K5 Operating Rm. 2nd Div. Operative Clinic, S. Dudley Guilford, M.D. and Staff.

11:00—Ward Rounds, S. Dudley Guilford, M.D. 9:00-12:00—K5 Operating Rm. 3rd Div. Operative Clinic, Arthur M. Wright, M.D., Robert Wadhams, M.D., William H. Barber, M.D. George A. Koenig, M.D.

11:30—Ward G6 Pediatric Clinic, Charles Hendee Smith, M.D.

Monday Afternoon

2:00-4:00-K5 Operating Rm. 4th Div. Operative Clinic, Carl G. Burdick, M.D., John H. Morris, M.D.

BETH ISRAEL HOSPITAL

Stuyvesant Park East

Monday Morning

9:00-1:00—Operative Clinics—

- 1. Harry E. Isaacs, M.D., and Staff.
- 2. DeWitt Stetten, M.D., and Staff.
- 3. Abraham Hyman, M.D., and Staff.

Monday Afternoon

2:00—Pediatric Clinic, Herman Schwartz, M.D.

2:00-Ward Rounds-Medical-

- 1. Isidore W. Held, M.D.
- Marcus A. Rothschild, M.D.

CITY HOSPITAL

Welfare Island

Monday Morning

9:00-12:00—Operative Clinic—Urology. Terry M. Townsend, M.D. and Staff.

Monday Afternoon

3:30—Dermatological Conference, A. Benson Cannon, M.D., Jerome Kingsbury, M.D.

COLUMBIA UNIVERSITY MEDICAL CENTER 168th Street at Broadway

9:00-10:30—Obstetrical Ward Rounds, Floor N (Presbyterian Hospital). William E. Caldwell,

M.D. 9:00-10:30-Obstetrical Ward Clinic, Floor O

(Presbyterian Hospital). William É. Caldwell, M.D.

10:45-12:00-Obstetrics, Demonstration Room, Floor O (Presbyterian Hospital), William E. Caldwell, M.D.

12:00-Lecture on Obstetrics, Amphitheater F (College of Physicians and Surgeons), Benja-

min P. Watson, M.D. 4:00-5:00—Medical Team Ward Rounds, Wards G & H Center (Presbyterian Hospital), Alphonse R. Dochez, M.D., and Staff.

4:00-5:00-Physiotherapy Lecture, Amphitheater A (College of Physicians and Surgeons), Nor-

man E. Titus, M.D.

5:00-6:00-X-ray Conference, X-ray Conference Room, Floor C (Presbyterian Hospital).

Auditorium 12:00-1:00-Psychiatry Lecture, (Psychiatric Institute), Clarence O. Cheney,

M.D. 2:00-Psychiatric Therapeutics (Psychiatric Institute), Clarence O. Cheney, M.D.

12:00-1:00—Pharmacology Symposium, Amphitheater N (College of Physicians and Surgeons), Harold T. Hyman, M.D.

2:00-Eye Operation, Operating Room (Eye Institute), Thomas H. Johnson, M.D.

General Surgical and Gynecological Operative Clinics as shown on the "Detail Sheets" of the Bureau for the day.

DEPARTMENT OF MALIGNANCY, DEPARTMENT OF HOSPITALS CANCER CLINIC

124 East 59th Street

II. Follow-up Clinics.

Monday Afternoon

2:00-Ira I. Kaplan, M.D., Director, and Staff. 4:00-I. Presentation of New Cases. Skin, Intra-oral, Breast, Uterine, Ovarian, Gastro-Intestinal, Uro-genital, Melanoma, Neuro-genie Sarcoma.

III. Clinical Conferences-Autopsied Cases.

a. Gross and microscopic specimens.

b. Roentgenology of the autopsied cases.

FLOWER HOSPITAL 450 East 64th Street

Diagnostic Medical Clinic, Linn J. Boyd, M.D. Clinic in Metabolism, Philip J. R. Schmahl, M.D. General Surgery, Walter Gray Crump, M.D. Genito Urinary Surgery, Joseph H. Fobes, M.D. and Louis Rene Kaufman, M.D.

Nose and Throat, J. A. W. Hetrick, M.D. Obstetrics, Henry B. Safford, M.D. Gynecology, Horace E. Ayers, M.D. Fractures, Milton J. Wilson, M.D. Brain and Neurological, K. Winfield Ney, M.D.

GERMAN POLYCLINIC 137 Second Avenue

Monday Morning

10:00-Hyman Biegeleisen, M.D., Varicose Vein Clinic with Demonstration of Technique of Injection and Treatment of Complications.

Monday Afternoon

2:00-4:00—Saul S. Samuels, M.D., Clinic Demonstration of Diagnosis and Treatment of Thrombo-Angeitis Obliterans and Related Disorders of the Circulation with lantern slides.

HARLEM HOSPITAL Lenox Avenue and 136th Street Monday Morning

10:30-Clinical Demonstration of Use of Oxygen in Tents and Chambers and Use of Serum in Pueumonia. Jesse G. M. Bullowa, M.D.

KINGS COUNTY HOSPITAL Clarkson Avenue, Brooklyn

Monday Afternoon

2:00-Surgery and Case Presentations, Nose, Throat and Ear Department, Mervin C. Myerson, M.D.

LEBANON HOSPITAL

Westchester, Cauldwell and Trinity Avenues

Monday Morning

Operative Clinic-Milton R. Bookman, M.D., and Staff; Philip M. Grausman, M.D., and Staff.

MANHATTAN EYE, EAR AND THROAT HOSPITAL

210 East 64th Street Monday Afternoon

2:00-Eye Clinic, Herbert W. Wootton, M.D.

2:00—Eye Operations, Lewis W. Crigler, M.D.

2:00—Ear Clinic, Arthur B. Duel, M.D.

2:00—Ear Operations, William H. Haskin, M.D.

2:00—Throat Clinic, Harmon Smith, M.D.

2:00—Throat Operations, Ebenezer R. Faulkner,

4:00-Demonstration of Cases of Tumors of Eye. Ear, Nose and Throat After Radium Treatment. G. Allen Robinson, M.D.

LINCOLN HOSPITAL

141st Street and Concord Avenue

Monday Morning

9:00-12:00—Operative Clinics, Kirby Dwight, M.D., Director of Surgery; Edward D. Truesdell, M.D.; William Bradley Coley, M.D., Benjamin Sherwin, M.D.; Charles S. Rogers, M.D.; James R. Lincoln, M.D.

MEMORIAL HOSPITAL

106th Street and Central Park West

Monday Morning

9:00-1:00—Operative Clinics—Neoplasms Stomach—George T. Pack, M.D. Intraoral—Hayes E. Martin, M.D.

9:00-11:00—Gynecological Examinations for Examining Room, William P. Neoplasm. Healy, M.D.

9:00-12:00-Follow-up Breast Neoplasm Clinic,

Burton J. Lee, M.D.; Frank E. Adair, M.D.

Monday Afternoon

2:00-4:00—Follow-up Rectal Neoplasm Clinic, George E. Binkley, M.D.; Melanoma and Neurogenic Sarcoma Follow-up Clinic, Frank E. Adair, M.D.

2:00-5:00—Operative Clinic, Head and Neck. Hayes E. Martin, M.D.

MOUNT SINAI HOSPITAL

1 East 100th Street

Monday Morning

9:00—Neuro-Surgical Operative Clinic, Ira Cohen, M.D.

9:00—Rare and Unusual Lesions of the Colon, Burrill B. Crohn, M.D.

9:00—Pediatric Clinic, Bela Schick, M.D. 9:30—Physiotherapy Clinic and Demonstrations, Heinrich F. Wolf, M.D.

9:00—X-Ray Demonstrations, Leopold Jaches, M.D.

Monday Afternoon

1:30—Operative Clinic, Robert T. Frank, M.D.

2:00—Operative Clinic, Richard Lewisohn, M.D.

2:00—Arterial Diseases, Eli Moschcowitz, M.D. 2:00—Interesting Medical Cases, Bernard S. Oppenheimer, M.D.

2:00—Hematological Clinic, Nathan Rosenthal, M.D.

2:00—Operative Clinic, Kaufman Schlivek, M.D.

2:00—Operative Clinic, Albert A. Berg, M.D. 2:00—Dermatological Demonstrations, Isadore

Rosen, M.D.

2:00—Operative Clinic, Edwin Beer, M.D.

2:00—X-Ray Demonstrations, Leopold Jaches, M.D.

NEW YORK EYE AND EAR INFIRMARY

13th Street and Second Avenue

Monday Afternoon

Ophthalmological Department

2:00-

1. Operative Clinic, Clyde McDannald, M.D., and Staff.

2. Clinical Demonstration of Intraocular Cases, Francis Shine, M.D., and Staff; Conrad Berens, M.D., and Staff.

Slide Demonstration of Pathological Eyes and Exhibit of Temporal Bones, Bernard Samuels, M.D., Edgar Burchell, M.D.

- Exhibit X-Ray Plates of Eye and Ear Cases, George S. Dixon, M.D.
- 4:00-1. Operative Clinic, Ben Witt Key, M.D.
 - Demonstration of Cases with Muscle Anomalies, Wendell L. Hughes, M.D.

Otological Department

2:00-Operative Clinic, Truman L. Saunders, 1. M.D., and Staff.

2. Case Demonstration Clinies. Stuart L. Craig, M.D., and Staff; Hugh Blackwell, M.D., and Staff.

4:00-Operative Clinic, James Morrisset Smith, M.D., and Staff.

Note: See Bellevue Hospital Schedule for Special Operative Clinics by Webb W. Weeks, M.D., and William B. Doherty, M.D., and Special Demonstrations by Sigmund Agatston, M.D., and Edward B. Gresser, M.D.

NEW YORK POLYCLINIC MEDICAL SCHOOL AND HOSPITAL

345 West 50th Street

Surgery

Monday Morning

9:00-10:00—Operative Gynecology, Louis J. Ladin, M.D.

10:00-11:00-Monilia Vulvo-Vaginitis (Lecture), Robert L. McCready, M.D.

11:00-12:00-Operative Surgery, J. Prescott Grant, M.D.

12:00-1:00-Demonstration of Fraetures, William V. Healey, M.D.

Monday Afternoon

1:30-2:30-Operative Proctology, Frank C. Yeomans, M.D.

2:30-3:30-Discussion of Obstetrical Forceps, Everett M. Hawks, M.D. and Edward H. Dennen, M.D.

3:30-4:30-Operative Urology, Daniel A. Sinelair, M.D.

4:30-5:30-Duodenal Surgery (Leeture, with lautern slides), Edward Leland Kellogg, M.D.

Medicine

Monday Morning

9:00-10:00-Allergy: Diagnosis and Technique (Lecture), Charles J. Dillon, M.D.

10:00-11:00-Medicine: Demonstration of Cases, Alexander Hofheimer, M.D.

11:00-12:00-Physical Therapy (Lecture and Demonstration on High Frequency Fever Treatment), Richard Koyaes, M.D.

Monday Afternoon

1:30-2:30-Insulin in Tuberculosis (Lecture, with Demonstration of Cases). Frederick M. Allen, M.D.

2:30-3:30-Demonstration of Cardiae Patients, Harold E. B. Pardee, M.D.

3:30-4:30-Pediatries: Demonstration and Discussion of Cases, W. Morgan Hartshorn, M.D.
4:30-5:30—Gastrie Mueosa Relief vs. Gastroscopic Examination (Illustrated), Samuel
Weiss, M.D.

Eye. Ear. Nose and Throat

Monday Afternoon

1:00-2:00—Rhinolaryngology (Lecture), W. Wallace Morrison, M.D. Torok, M.D.

2:30-3:00—Operative Rhinolaryngology, William 4:00-5:00—Operative Otology, John McCoy, Lawrence Gatewood, M.D.

3:00-4:00—Operative Ophthalmology, Ervin

NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL 303 East 20th Street

M.D.

Monday Morning

9:00-11:00-Amph., Operative Clinic, Thomas

H. Cherry, M.D. 9:00-11:00-Rm. 4, Operative Clinic, John J. Moorhead, M.D.

10:00-11:00—Amph. B, Clinical Lecture in Gynecology, Emil A. Rundquist, M.D. 11:00-12:00-Amph. C., Clinical Lecture in Trau-

matic Surgery, Henry H. Ritter, M.D. 12:00-1:00—Amph. D, Demonstration of Pediatric Cases, Roger H. Dennett, M.D.; Marshall C. Pease, M.D.; Adolph G. DeSanctis, M.D.; Moses H. Edelman, M.D.

12:00-1:00-X-ray Lab., General Roentgen Interpretation, William H. Meyer, M.D.

Monday Afternoon

2:00-4:00-Rm. 6, The Prostate and Seminal Vesicles; Their Pathology, Bacteriology, Instrumental Study of the Seminal Vesicles and Endoscopic Revision of the Obstructing Prostate, Joseph T. McCarthy, M.D.

2:00-4:00-Rm. 4, Operative Clinic, Fred H. Albee, M.D.

- 2:00-4:00—Skin Clinic—Case Demonstrations in Dermatology, George Miller MacKee, M.D.
- 2:00-3:00—Amph. C, Case Histories—Surgical Diagnosis, Ralph R. Moolten, M.D.
- 2:30-3:30—Rm. 2, Otological Operative Clinic, Clarence H. Smith, M.D.
- 2:30-3:30—Ear Clinic, Clinical Demonstrations of Otologic Cases, Clarence H. Smith, M.D., and Staff.
- 3:00-5:00—Amph., Operative Clinic, John D. Stewart, M.D.
- 4:00-5:00—Amph. D., The Treatment of Coronary Thrombosis, Robert H. Halsey, M.D.
- 4:00-5:00—Amph C., The Treatment of Infantile Paralysis, George Anopol, M.D.
- 4:00-5:00—Amph. A., Clinical Demonstration on Preventive Medicine, C. Ward Crampton, M.D., and William H. Park, M.D.

ROOSEVELT HOSPITAL

59th Street at Ninth and Tenth Avenues
Monday Morning

9:00-12:30—Operative Clinics—

- 1. Alfred Stillman, M.D., and W. Crawford White, M.D.
- 2. Henry W. Cave, M.D., Kirby Dwight, M.D., and Condict W. Cutler, Jr., M.D.

ST. FRANCIS' HOSPITAL

East 142nd Street and St. Ann's Avenue Monday Morning

9:00—Operative Clinics—

- 1. Thomas H. Russell, M.D., and Staff.
- 2. Francis Edgerton, M.D., and Staff.

ST. LUKE'S HOSPITAL

421 West 113th Street

Monday Morning

9:00-12:00—Operative Clinics—

1. Henry H. M. Lyle, M.D., and John Douglas, M.D., and Staffs.

2. Walton Martin, M.D., and Frank S. Mathews, M.D., and Staffs.

SEAVIEW HOSPITAL

(Tuberculosis)

Brielle Avenue, West New Brighton, S. I.

Monday Afternoon

2:00-4:00—Urological Tuberculosis Case Presentation, Arthur J. Greenberger, M.D., Monroe E. Greenberger, M.D., Leonard P. Wershub, M.D.

Those desiring to attend are requested to tele-

phone to Dr. Arthur Greenberger, Regent 4-7146 for directions as to transit.

2:00-4:00—Operative Clinic Thoracic Pulmonary Tuberculosis, William F. Honan, M.D.

Those desiring to attend are requested to telephone to Dr. William F. Honan, Butterfield 8-2343 for directions as to transit.

STUYVESANT SQUARE HOSPITAL

301 East 19th Street

Monday Aternoon

2:00-4:00—Dermatological Clinic. Cases from the services of Jerome Kingsbury, M.D., Binford Throne, M.D.

WOMAN'S HOSPITAL

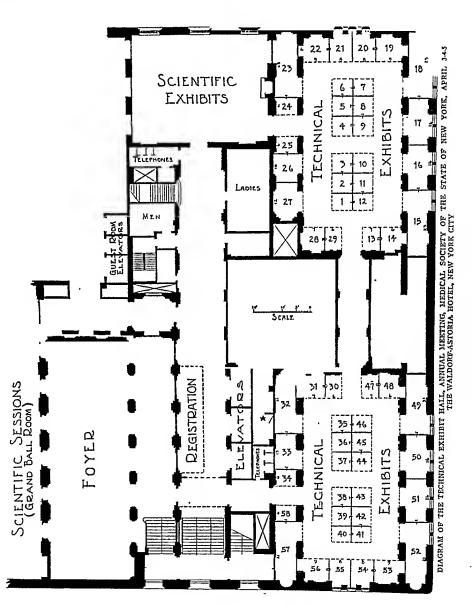

110th Street and Amsterdam Avenue

Monday Morning

Monday Afternoon

8:30—Operative Clinic — Reginald M. Rawls, M.D., and Staff.

2:00—Operative Clinic—Byron H. Goff, M.D., and Staff.

THE TECHNICAL EXHIBITS

Booth 27—American Agency of French Vichy, Inc., New York, N. Y. will exhibit Vichy Célestins Water, bottled at the Spring, Vichy, France, famous as a health resort.

In 1918 Vichy was turned into a large military hospital center for the American Army.

Vichy owes its prestige to the high approval of the medical profession.

Last year Vichy was the meeting place of the great International Congress of Biliary Lithiasis, attended by over 1,200 doctors.

The Vichy Exhibit includes Vichy Waters, Vichy Salts and Pastilles made from the salts extracted from the Vichy Waters.

Photographs of the scientifically equipped therapeutic establishments at Vichy will be shown.

2110 1111

Booth 48—American Vitamins Incorporated,

New York, N. Y.

Bemax is a natural concentrated vitamin B food consisting of selected cereal germ, biologically tested for high vitamin B content, and stabilized to prevent deterioration and rancidity. Bemax assays over 1400 Sherman-Chase units of vitamin B per ounce; it is likewise rich in vitamin G and E, and in the tissue building substances and growth factors of the cereal embryo.

The exhibit will demonstrate the pathology of chronic vitamin B deficiency, with special reference to its effect upon gastro-intestinal structure and function. It will also demonstrate the vitamin B content of the "well balanced" diet and the effect of supplementing it with Bemax, and the comparative superiority of Bemax as a source of vitamin B.

Booth 18—Anglo-French Drug Co., Inc., New York, N. Y., will exhibit their therapeutic products, among which will be *Stamoxyl* for the treatment of boils.

Booth 58—P. Beiersdorf & Co., Inc., New York, N. Y., will present physicians and their wives visiting their booth with a jar or tube of Nivea Creme. Physicians like this new type emollient creme, prepared from Aquaphor, for the care of their hands, and will welcome Nivea Creme for their wash-up basin. To women, Nivea appeals as an all-round economic cosmetic creme.

Special demonstration will be given of *Elastoplast*, a new elastic adhesive bandage for support and compression. *Elastoplast* is now made available at prices permitting of widest use in surgical, industrial and general practice.

Booth 36—Bilhuber-Knoll Corp., Jersey City, N. J., will display in Booth 36 a complete

line of its medicinal chemicals, which include some important new therapeutic agents.

Dilaudid, the new morphine derivative, possessing many advantages over morphine and the other opiates in control of pain and cough, is an important new development. Phyllicin, the new well-tolerated theophylline salt for oral medication, will also be exhibited. Such well-known medicinal specialties as Theocalcin and Metrazol and Eurcsol, so widely used in scalp lotions, will be displayed. Also Bronural, the sedative and hypnotic that is neither a bromide nor a barbituric acid derivative.

Booth 31—Cameron's Surgical Specialty Co., Chicago, Ill., will demonstrate the application of electric light in scopes, retractors, speculæ and lamps for use in diagnosis, treatment and surgery throughout the body, with the Electro-Diagnostoset. Of particular interest is the Tele-Vaginalite, the new vaginal speculum with 10x telescope for the early determination of cervical malignancies. Here, too, will be shown Cameron's Cauterodyne with the new handle control enabling the surgeon to secure any desired amount of current at any stage of any operation—the latest idea in electro-surgery.

Booth 47—S. H. Camp & Company, Jackson, Michigan, will display Camp Physiological Supports for Maternity. Post-Operative, Ptosis, Hernia and Orthopedic conditions. Each model is designed for a distinctive function and a particular purpose, all having the patented continuous lacing feature essential in securing the best results.

Very few physicians or surgeons are unfamiliar with Camp Supports, but by stopping at the booth, you can acquaint yourself with the newest principles in design developed in conformity with the latest physiological and scientific advancement.

Booth 12—Comprex Oscillator Corporation, New York, N. Y.

Booth 20—Crookes Laboratories, Inc., New York, N. Y., will exhibit *Collosol* preparations—an ethical line of stable colloidal products for medicinal use. Physicians will be given an opportunity to study various colloidal phenomena and their relation to therapeutics.

Several new specialties will be introduced to the profession at this time, among them, Collosol brand Sodium Morrhuate, Collosol brand Halibut Liver Oil, and a new stable preparation of high calcium content for intramuscular or intra-

venous use.

The exhibit will be in charge of members of the scientific staff under the direction of Mr. F. L. Cheney. Booth 10—R. B. Davis Company, Hoboken, N. J., invites visiting physicians and their friends to enjoy a glass of refreshing, delicious Cocomalt, which has become so popular and acceptable to the members of the medical profession.

Cocomalt is accepted by The American Medical Association Committee on Foods, and is licensed by the Wisconsin Alumni Research Foundation under Steenbock Patent. Each ounce of Cocomolt, the amount used in an ordinary serving, contains as much Vitamin D as two-thirds of a teaspoonful of standardized cod liver oil.

A cupful of *Coconnalt*, taken hot before retiring, tends to induce sleep. Its nourishing qualities not only soothe the digestive tract, but supply the system with energy against the coming day's work.

Booth 42—The Denver Chemical Mfg. Company, New York, N. Y. will exhibit Antiphlogistine in Space 42. Antiphlogistine, which has been ealled "inflammation's antidote" and "the perfect poultice," is forty years old. It is employed by physicians in all parts of the world. There is only one way in which an ethical product can attain this distinction, and that is through merit. It is always well to remember that Antiphlogistine has never been successfully imitated. Physicians are invited to visit the exhibit and register for a package of Antiphlogistine.

Booth 30—The DeVilbiss Company, Toledo, Ohio, manufacturers of medicinal otomizers, has reserved Space No. 30 at the Annual Convention of the Medical Society of the State of New York, to be held at the Waldorf-Astoria, New York City, April 3-5, 1933. A complete line of DeVilbiss Atomizers and Vaporizers (Nebulizers) will be displayed. F. L. Graham will be in charge. All delegates to the convention are cordially invited to visit this exhibit.

Booth 3—H. T. Dewey & Sons Company, New York, will exhibit its well-known grape juice, and also its combination with other pharmacal products. The juice is extracted without the use of heat, thereby retaining the constituents in their natural state.

Dewey also combines grape juice with mineral oil, and agar-agar under the name *Grape Minol*. The mixture has the natural flavor of the grape juice with the therapeutic properties of the agar and oil.

Samples of the natural juice and the *Grape Minol* will be dispensed to the guests calling at Booth 3.

Booth 17—The Doak Company, Cleveland, Ohio, has an interesting exhibit of various colloidal preparations for the treatment of lues,

anemia, and particularly chronic arthritis. An article on colloidal sulfur in the treatment of arthritis appeared recently in the Journal of Bone and Joint Surgery. The author states colloidal sulfur has a definite place in the treatment of arthritis. Every progressive physician is interested in this obscure disease and is eager to help his suffering patients. Dr. George Rasch and Wm. H. Puls will be present to give information on the value of colloids in various afflictions. Reprints on the elinical application of colloids will be obtainable at Booth 17.

Booth 53—The Drug Products Co., Inc., Long Island City, N. Y., will exhibit a selected line of pharmaceuticals.

Of particular interest will be the display of an extensive and distinctive group of colloidol preparations. The chief chemist will be present to explain the reasons for the increasing recognition of the therapeutic value of colloidality. An ultra-microscope will afford physicians the opportunity to see the Brownian movements of colloids

Another feature of the booth will be a display of *Pulvoids*, which approximate capsule medication in tablet form—one of the distinct advances in pharmaceutical manufacturing technic that has built the reputation of the Drug Products Co., Inc., as a leader in the field.

Booth 52—The Ferment Company, New York, N. Y., will demonstrate its acidolphilus milk and explain the standard method of its use in correcting intestinal putrefaction.

Booth 9—Fremont Canning Company, Fremont, Michigan, will show a new Gerber Product—Strained Cooked Cereal—used for postoperative, ulcer, colitis, and gastro-intestinal cases where a bland diet is indicated. Thorough cooking, fine straining, additional Vitamin B (from wheat germ), combined with uniformity, make a starting cereal for infant feeding. We invite you to inspect this cereal and also Gerber's Strained Vegetobles.

Booth 57—The Foregger Company, New York, N. Y., will have a comprehensive display of apparatus for anesthesia, resuscitation, and oxygen therapy in booth 57. This will include the Gwathmey and the Metric Gas Machines, and the new Waters Metric Anesthesia Table which combines the gas machine, blood-pressure apparatus and the anesthetist's table in one compact unit. The Henderson and the Flagg Resuscitation Apparatus and a number of oxygen-carbondioxide outfits on the "make-yout-own-mixture" principle will also be shown.

Booth 4—Gallia Laboratories, Inc., New York, N. Y., will exhibit two Council-accepted specialties, *Arheol* and *Riodine*.

Arheol (Astier), which is the active principle of sandalwood oil, insures uniform results in gonorrhea and other inflammations of the urinary tract and without irritating either the stomach or the kidneys.

Riodine (Astier) provides a very effective form of iodine medication that reduces the danger of iodism to a negligible factor.

Visiting physicians will receive samples.

Booth 7—Harold Surgical Corporation, New York, N. Y., will have a most complete and interesting exhibit of *Ultra Violet Ray Equipment*. It will show for the first time a new *Mercury Quartz Lamp*, that is beautiful in appearance, efficient in operation, and low in price. The exhibit will also include Carbon Arc Lamps and General Electric Co. Type Bulb Lamps. They will cover a price range of from \$7.50 to \$650.00. In addition it will exhibit the latest innovations in surgical instruments and physicians' supplies.

Booth 44—Health Products Corporation, Newark, N. J., has an exceptionally interesting display on White's Cod Liver Oil Concentrate Tablets. Here you will find clearly demonstrated what is meant by the vitamin fraction (non-saponifiable fraction) of cod liver oil, which makes it easy to understand the principle of how cod liver oil can be concentrated.

A number of reprints of good clinical studies on cod liver oil and cod liver oil concentrates are also available at the booth.

Booth 14—The Heidbrink Company, Minneapolis, Minn., will exhibit its specialties.

The latest model Oxygen Tent. Mr. Grimm will explain its technique and operation.

Anesthetizers, from the small Junior Portable (not a toy) to the three and four gas Lundys, all reliable and durable.

Analgesia,—surgeons and even the public are demanding it. Our representatives will demonstrate it anywhere on practical cases with Heindbrink Company.

Automatic Obstetrical Portable outfits will also be shown.

Booth 24—Hoffmann-La Roche, Inc., Nutley, N. J. Pantopon, the injectable whole-opium product about which so much has been written in recent months, will be one of several Hoffmann-La Roche "Medicines of Rare Quality" featured at Booth 24. Members of the "Roche" Scientific Department will be glad to talk to you and answer any questions about Pantopon, Allo-

nal, Alurate, Digalen, Sedormid, Sedobrol, Elixir Arsylen Compositum and the other remedies which will be displayed.

Booth 33—The Horlick's Malted Milk Corporation, Racine, Wisconsin will exhibit Horlick's Malted Milk, natural and chocolate flavors, and Horlick's Malted Milk Lunch Tablets in the same flavors. Horlick's Maltose and Dextrin Milk Modifier is also on display, which has achieved a marked success for use in infant feeding. Glassine envelopes containing tablets will be distributed to visitors.

Some of the special uses for *Horlick's Malted Milk* which will be emphasized are the following:

- (1) For sleeplessness.
- (2) For infant feeding.
- (3) In digestive disorders.
- (4) During influenza and wasting diseases.
- (5) In nervous cases.(6) In convalescence.
- (7) For the undernourished.
- (8) For nursing mothers.

Booth 8—The Hydrosal Company, Cincinnati, Ohio, will demonstrate the vast difference between true Burow's Solution—a perfect colloidal suspension—and the ordinary extemporaneous "solutions" so frequently employed.

Note the crystal clarity of *Hydrosal* as contrasted with the milkiness of the usual type of preparation. Also note the absence of certain impurities in *Hydrosal*, such as free lead.

Hydrosal is the true colloidal suspension of aluminum acetate which is being so extensively used as a wet dressing and ointment in dermatology, eye-ear-nose and throat work, and pediatrics.

Booth 35—Kalak Water Company of New York, Inc., New York, N. Y. Physicians are invited to visit Booth 35 and test the palatability of Kalak Water. Many physicians who have frequently prescribed Kalak Water are familiar with its value as an alkalinizing agent.

Visit the Kalak booth and discover how delicious and refreshing Kalak is when it is prop-

erly served.

Booth 11—Kellogg's, Battle Creek, Michigan, will demonstrate the value of All-Bran in the low calory diet. A comparison of two tablespoonfuls of All-Bran with other commonly used foods will be shown in an interesting display...

Kaffee Hag Coffee and All-Bran Cookies will be served at the booth to visitors. Kaffee Hag is coffee which has had 97 per cent of the caffeine removed. It is used in diets where stimulants are undesirable. Mrs. Winifred Loggans of the Home Economics Department will be in charge.

Booth 23-A—The C. F. Kirk Company, Bloomfield, N. J., manufactures solutions for intravenous and hypodermie injections, to be used only by physicians.

It also manufactures vaccines of individual organisms, so that the doctor may now make his own mixtures by using varying amounts of vaccine to suit the particular case. The methods of preparation of these vaccines have been passed upon and accepted by the United States Public Health Service, for which they were granted license No. 105.

The company manufactures its products under scientific supervision in a modern laboratory, well equipped for sterilization and asepsis. It has adopted the slogan "Medication for the Physician's Use,—Not to Exploit the Physician."

Booths 28-29—Lederle Laboratories, Inc., New York, N. Y., will feature Solution Liver Extract for intramuscular injection. This product provides in a 3 c.c. vial the active material from 100 grams of fresh liver. It is specific in pernicious anemia.

It will also show Pollen Antigens for hay fever, Antipneumococcic Serum for pneumonia, Erysipelas Antitoxiu for erysipelas, and Digitalis Tablets, prepared from whole leaf, in accord with the suggestions of the New York Heart Committee and standardized in cat units.

Visitors should see everything that Lederle has to offer, as it aims to make the exhibit educational.

Booth 39—J. B. Lippincott Company, Philadelphia, Pa., will feature the Every Doy Practice Series, edited by Harlow Brooks, consisting of monographs on important every day subjects by eminent writers. The binding of these volumes is a reproduction of a celebrated hand-tooled leather binding of 1499.

The company will also display the new Fuchs' Diseoses of the Eye, translated by E. V. L. Brown; the new Operative Surgery by Kirschner, translated by Raydin of the University of Pennsylvania, familiarly known as the Color Surgery; Children's Tonsils In or Out by Kaiser; Surgical Errors ond Sofeguords by Thorek; and Tumors of the Breost by Cheatle and Cutler.

Booth 22—Mead Johnson & Company, Evansville, Indiana, will have on exhibit its complete line of infant diet materials, including Meod's Dextri-Moltose, Meod's Viosterol in Oil 250D, Meod's A-D Viosterol in Holibut Liver Oil, Meod's Undiluted Halibut Liver Oil, Mead's Newfoundland Cod Liver Oil, Meod's 10D Cod Liver Oil with Viosterol, Meod's Brewers Yeost Tablets, Meod's Powder, Mead's Brewers Yeost Tablets, Meod's Cereol, Sobee, Mead's Powdered Whole Milk, Alacta, Mead's Powdered Protein Milk, Mead's Alacta, Mead's Powdered Protein Milk, Mead's

Powdered Lactic Acid Milk, Recolac, Casee, and Mead's Mineral Mixture Tablets.

There will also be for the examination of plysicians a complete line of *Mead's Services*, such as diets for older children, height and weight charts, etc., all of which are free to members of the medical profession in any quantity desired.

Representatives will be on hand to meet their friends and to discuss the application of any of the Mead products to infant feeding problems.

Booth 34—Mellin's Food Company, Boston, Mass., will exhibit its well-known line of foods for babies.

Booths 5-6—Merek & Company, Inc., Rahway, N. J., will display such well-known preparations as: Pyridium for the treatment of urinary infections, Neoarsphenomine for the treatment of syphilis, Tryporsamide for the treatment of paresis, Stovarsol for amebic dysentery, Digitan for heart diseases, Erythrol Tetranitrate for hypertension, Bismosol, a water-soluble preparation for intransuscular use in syphilis, and Arsenoferratose, a palatable blood building tonic. There will also be shown a number of new preparations such as Clymocol for the extemporaneous preparation of stable surgical solutions.

Booth 26—Merckens Chocolate Co., Inc., Buffalo, N. Y., will exhibit its Malteao, manufactured from malt and cacao (cocoa). It also contains milk and sugar in proper proportions; but what makes this product especially valuable are the organic salts of iron, calcum and phosphate contained therein. We lay particular stress upon the word "organic" since these salts have been extracted from vegetable products, which fact makes them digestible. They are readily assimilated into the system.

An analysis shows that *Malteao* contains about 26 times as much fron in organic form as is contained in spinach and more than twice as much calcium as you will find in milk, and about four times as much phosphorus as is contained in eggs. Besides, *Molteoo* contains diastase, which helps to digest starchy food.

Booth 21—The exhibit of the Metropolitan Life Insurance Company, New York, N. Y., will show the response to the individual magazine advertisements of the company on Heart Disease, Periodic Health Examinations, Tuberculosis, Overweight, and other health and disease subjects as measured by the number of requests received for explanatory literature.

Booth 19—Mutual Pharmacal Co., Syracuse, N. Y, is exhibiting products of its laboratory, including a number of new preparations which will be of interest to physicians. Samples of these

preparations will be offered to those interested. Physicians are invited to visit the booth and secure samples or information regarding the Company and its products.

Booth 56—The E. L. Patch Co., Boston, Mass., will show Patch's Flavored Cod Liver Oil, which is well-known to the medical profession of New York State. The exhibit will show the recent developments in the cod liver oil field, and their representatives will be on hand to give information and to answer questions regarding Patch's Flavored Cod Liver Oil.

In addition there will be on display an interesting exhibit of Patch's Kondrenul—the Irish moss mineral oil emulsion. Kondrenul is a superior mineral oil emulsion—the result of more than two years of scientific research in the Patch Company Colloid Laboratory. At the Patch booth you will learn why there is no leakage when Kondrenul is prescribed in the treatment of constipation.

Booth 51—Picker X-Ray Corporation, New York, N. Y., will show several of the new developments in x-ray equipment. Featured among these will be the new Shock Proof Fluoroscopes.

Although 87,000 volts are used for fluoroscopy, these new fluoroscopes afford absolute protection from high voltage electrical shock to the patient, operator and observer.

You are cordially invited to attend.

Booth 45—The Chas. H. Phillips Chemical Co., New York, N. Y. Effective, palatable, convenient are qualities typified in *Phillips' Milk of Magnesia Tablets*. Each tablet contains 4.8 grains of freshly precipitated Magnesium Hydroxide in its highest purity, the magnesia equivalent of one teaspoonful of *Genuine Phillips' Milk of Magnesia*. We should like to have you try *Phillips' Milk of Magnesia Tablets*, a product of acknowledged utility which is growing steadily in professional favor. Samples may be obtained at Booth 45.

Booth 2—Radon Company, Inc., New York, N. Y., will demonstrate the latest type of instruments for use with *radon*. The use of radon for topical, cavity, and interstitial radiation will be explained.

Physicians are cordially invited to call at Booth 2 and discuss their radiation problems with the Company's experts.

Booth 13—Sanborn Company, Cambridge, Mass., will show its Motor-Graphic Metabolism apparatus, which embodies the three essentials of accuracy of design, durability of construction, and simplicity of operation. The '33 model features quiet-running motor-blower circulation of

oxygen, providing easy breathing; the oxygen shut-off valve, for economy as well as ease of operation; and other interesting features.

The Sanborn Battery-Operated or Electric-Portocardiografs are conveniently portable in two compact carrying cases. The three-second interval time marker, the ready autograf, the lead length regulator, the visual string tension control, and double speed device are some of the exclusive Sanborn features.

Booth 1—Sandoz Chemical Works, Inc., New York, N. Y., will be represented by men familiar with technical subjects and competent to answer questions concerning the five Councilaccepted preparations to be shown. A special feature will be Calglucon, a calcium salt suitable not only for oral and intravenous use, but also for intramuscular administration,—an outstanding advantage. Another product of merit is Gynergen (Ergotamine), a pure, specific alkaloid of ergot. Gynergen is recommended to take the place of fluidextract of ergot, just as morphine has largely displaced opium galenicals.

Booth 50—Saratoga Springs Commission, Saratoga Springs, N. Y., will exhibit photographs and charts showing the treatments that are given at the State Sanatorium.

Booth 25—The W. B. Saunders Company, Philadelphia, Pa., very cordially invites all members to visit Booth 25, at which the full Saunders list will be on exhibit. Your particular attention is invited to the numerous new 1933 books, including the new Volume VII of Bickham's Surgery. Full information and advance prospectuses of the following important books that are in active preparation for early publication will be shown: Curtis, Gynecology and Obstetrics, three volumes; Hinman, Urology; Collander, Applied Anatomy; Mitchell, Pediatrics; and several others. The exhibit will be in charge of T. H. McKenna, who will endeavor to extend every courtesy to all visitors.

Booth 41—Schering Corporation, New York, N. Y., will show the following products:

Progynon, a standardized follicular sex hormone, in tablet and ampule form, the first preparation to be standardized for oral use. Progynon is used in the treatment of deficiencies of female sex glands in amenorrhea, dysmenorrhea, and menopausal conditions.

Neo-Iopax, a material used intravenously to produce an opacity of the urinary tract in making

x-ray pictures for diagnostic purposes.

Saráka, a new remedy for the treatment of habitual constipation, which has greater swelling power than any other product used for this purpose, and at the same time produces a tonic condition of the intestines which promotes motility.

Nioza, the latest azo dye material perfected by Schering for infections of the genito-urinary tract. It is effective in both acid and alkaline medias, and acts as a sedative and bacteriostatic agent.

Booth 46—S. M. A. Corporation, Cleveland, Ohio.

Vitamin A crystals were so rare only three years ago that few men in the whole world had seen them. Now, they will be shown by S. M. A. Corporation, in Booth 46.

The company has recently offered physicians caratene (primary vitamin A) in four forms: as crystals, in vegetable oil, in cod liver oil, and with natural vitamin D. The natural vitamin D is a highly potent antirachitie agent prepared by methods (Zucker process) developed at Columbia University. It is offered alone and in combination with carateue.

S. M. A. Corporation is also showing its old reliable antirachitic breast milk adaptation, S. M. A. Specimens of breast milk fat and S. M. A. fat will be available for the purpose of comparison. Alerdex, the new protein-free maltose and dextrins preparation for all milk modification purposes, as well as Smaco Hypo-Allergic Milks, will also be exhibited.

Visit Booth 46; see the caratene crystals and get detailed information.

Booth 55—C. M. Sorensen Co., Inc., Long Island City, N. Y., intends having on display for your personal inspection several new features which will be highly useful to the medical profession, and especially to the men interested in ear, nose and throat work. These will include a new model, No. 54, two-cylinder treatment outfit complete, the DeLuxe, Junior, and the very efficient heavy duty large silent four-cylinder, suction and treatment apparatus, No. 405, which has proven so popular. The company will also show a number of new combinations, and improved and modified outfits, each attractive in its own way.

Booth 40—Tailby-Nason Company, Cambridge, Mass., will again present Nason's Palatable Cod Liver Oil. Real fishing scenes from the Lofoten Islands of Norway where Nason's Plants

are located are on exhibit. The Giant Cod is also on hand to greet you.

Booth 37—George Tiemann & Co., New York, N. Y., will show newly designed instruments for living sutures. The use of these new instruments facilitates not only obtaining the fascia, but the special needle makes it easy to use, with a minimum waste of suture, and with a minimum of suture trauma.

A superior stainless steel hypodermic needle, which will not break in use, has a keen point and is perfectly smooth inside and out, will also be

featured in the Tiemann exhibit.

Booth 54-Myron L. Walker Co., Inc., Mt. Vernon, N. Y.

Booths 38 and 43—The Wander Company, Chicago, Ill., invites you to visit its booths whenever you feel tired or "on edge" and partake of a cup of refreshing Ovaltiue, the well-known Swiss Food Drink for nervousness and fatigue. Ovaltine is used as a soft or liquid diet in difficult feeding cases, such as gastrie conditions, and for malnutrition, and convalescence, and for nursing mothers. In the home it is used for sleeplessness and as a mealtime beverage instead of tea or coffee. Feel free to visit Mr. Jenkins at the Ovaltine booth frequently.

Booth 16—Winthrop Chemical Company and H. A. Metz Laboratories, New York, N. Y. This joint exhibit includes a number of the older standard products of the Winthrop Chemical Company, such as Luminal and Luminal-Sadium (tablets and ampules) and Theocin, and of the H. A. Metz Laboratories, such as Pyramidan and the Salvarsans. Your attention is also called to the anesthetic group—Avertin for basal anesthesia, Navoccin Crystals, Spinacain and Pantacain for spinal anesthesia; also Pantacain solutions for topical application. Furthermore, the display includes Theominal for hypertension; Synadal for the treatment of peptic ulcer; Neoskiodon, the new radiopaque agent for intravenous urography; and Solyrgan, the powerful diuretic.

Booth 49—W. D. Allison & Co., Indianapolis, Indiana, will show its line of office furniture and equipment.

LEGISLATIVE BULLETIN NUMBER 5

February 10, 1933.

Action on Bills

Senate Int. No. 142—Berg, to permit restoration by Regents of a license to practice medicine to a person pardoned after conviction of felony, for misconduct in his professional capacity, has passed the Senate and been referred to the Assembly Committee on Education.

Senate Int. No. 426-Twomey, relative to sale

of poisonous or habit-forming drugs or chemicals, has been advanced to third reading in the Senate.

Hearings

February 21—Committees on Codes—Joint Hearing.

Sen Int No 144—Esquirol Assembly Int No 75—Kan towski

Sen Int No 456—Berg Assembly Int No 145—Theo dore

Vew Bills

Senate Int No 703—Quinn, to amend the Criminal Code relative to proceedings when a person in confinement appears to be instance or a mental defective Referred to the Codes Committee This bill differs slightly in its wording being a little broader thrui Senate Int No 624—Quinn, Assembly Int No 781—Robinson, but the intent of the two bills is the same

Senate Int No 711—Byrne, adds new article to the Public Health Law for governing sale and distribution of ive and other caustic substances in containers for household use. Referred to the Health Committee. A law similar to this has been enacted by almost every. State in the Union within the last five years. We have liad many requests from physicians in neighboring States asking that a hill similar to this be proposed and enacted. Particularly, have these requests come from eye, ear nose and throat specialists.

Senate Int No 732—Cilnno, Assembly Int No 922—Marks, to amend the Vehicle and Traffic Law and Tax Law, by exempting from payment of registration fees on a motor vehicle owned by an individual, corporation or association and used exclusively for eleemosynary or charitable work, or to vehicles owned by a sewer or water district, and by providing for refund of motor fuel tax paid on account of vehicles used for charitable purposes Referred to the Internal Affairs Committee This bill would except ambulances from payment of registration fee

Senate Int No 757—Evans adds new section to the Public Welfare Law for central bureau of hospital clinics in each public welfare district to promilgate rules for persons applying for treatment in hospital clinics. Referred to the Health Committee. There has been much complaint from

New York City and other sections of the State of abuse of clime privileges. This amendment would set up additional inachinery for supervising clinic admissions.

Sente Int No 788—Berg, to mend the Ldu cuton Law by providing certain acts of Regents iffecting the professions must first be recommended by board of examiners of the profession involved. Referred to the Education Committee I his bill provides that the Regents shall secure a recommendation from the board of examiners before accepting from applicants for licensure evidence of preliminary and professional education or endorsing a license issued by some other state or country, or to endorse a certificate of rich ibilitation of the United States Veterans' Burgan

Senate Int No 810—Mastick, to amend the I ducation Law by requiring plans and specifications for new school buildings to assure proper ventilation instead of at least 30 cubic feet of pure air every minute per pupil and striking out provision on foul air Referred to the Education Committee

Assembly Int No 970—Mr Cuvillier has in troduced the following garnishee bill

"AN ACT to amend the Civil Practice Act in relation to less upon earnings or meoine of judgment debtor

"Section 1 Section six hundred eighty-four of the Civil Practice Act is hereby amended by inserting therein a new subdivision to be subdivision eight to read as follows

'8 No execution under this section shall be issued, except to satisfy a judgment entered upon indebtedness hereafter incurred for failure to just for the necessaries of life including rent of a dwelling, board and lodging, food clothing drugs or medicines, or professional services rend ered by a physician, dentist or lawyer

"This act shall take effect immediately Referred to the Codes Committee"

In a previous bulletin we stated that the American Medical Association had approved the Dickey narcotic drug bill, Assembly Int No 395 Since issuing that bulletin we have been informed by Dr Woodward, of the AMA, that we were technically not correct. Neither the house of delegates nor the board of trustees has ever passed upon the bill, bit drafts of it have been sent out by the AMA to the various State medical societies showing its stages of development and so far as practicable the suggestions offered by representatives of such associations have been incorporated into the bill

Information has reached us from several sources that the intent of the Public Welfare I aw

* * *

which was enacted two years ago, is being lost in its administration. You will recall that while the amendment was in process of enactment, we stressed forcibly that its administration would differ from that of the old Poor Law in that the family physician was to be given preference in providing services for the indigent. We insinuated that it was quite likely there would be difficulty in some sections of the State in bringing about such a drastic change, but felt it wouldn't be impossible. Our latest information from the State Department of Social Welfare is that a great improvement in the care of the indigent has resulted from the administration of this law; but recently, as was said above, it has been reported that in certain towns the commissioner of public welfare has discontinued the employment of family physicians and engaged with one physician to do all of the work. The principal reason for changing is an effort on the part of the commissioner to cut down expenses, but, unfortunately, the amount of medical work to be done will not have decreased and the result will be that if the indigent are to receive the same care, the appointed physician will be obliged to render services at a rate of fees far lower than that recommended by the Economics Committee, or other physicians will take care of some of the indigents and receive no pay.

Having secured the enactment of a law which assured a very definite advancement in the medical care of our indigents, it now seems important that the Medical Societies should exert themselves to maintain the effectiveness of this law.

LEGISLATIVE BULLETIN NUMBER 6

February 17, 1933.

Action on Bills

No action was taken on any of the bills in which we are interested since the issuance of the last bulletin.

Hearings

February 21—Committees on Codes—Joint Hearing.

Senate Int. No. 604—Slate; Assembly Int.

No. 780—Robinson.

Senate Int. No. 622—Quinn; Assembly Int. No. 785—Robinson.

Senate Int. No. 624—Quinn; Assembly Int. No. 781—Robinson.

Assembly Int. No. 782—Robinson.

Assembly Int. No. 783—Robinson.

Assembly Int. No. 783—Robinson.

Postponed from February 23rd—
Committees on Labor and Industry—Joint Hearing.

Senate Int. No. 139—Nunan; Assembly Int. No. 72—Cooney.

Assembly Int. No. 130—Breitenbach.

Senate Int. No. 144—Esquirol; Assembly Int. No. 75—Kantowski.

Senate Int. No. 145—Theodore.

Senate Int. No. 145—Theodore.

Senate Int. No. 147—Schackno.

Assembly Int. No. 147—Schackno.

Assembly Int. No. 147—Schackno.

Assembly Int. No. 63—Vaughan (Antivivisection bill)

Assembly Int. No. 181—Bernhardt (Antivivisection bill)

New Bills Introduced

Senate Int. No. 924—Schackno; Assembly Int. No. 1130—Close, adds new section to the Lien Law for liens of hospitals for care and treatment of certain injured persons. Referred to the Judiciary Committee. This bill is very similar to

Mr. Close's bill, Assembly Int. No. 131, except that it limits the actions to accounts where the injured person receives an amount in excess of \$200.00 in settlement for the injury.

Senate Int. No. 929—Howard; Assembly Int. No. 779—Kirnan, to amend the Civil Service Law by providing no person shall be appointed to position in classified service unless he is a citizen of U. S. and has been resident of state for at least five years preceding appointment or application for examination. Referred to the Civil Service Committee.

Senate Int. No. 993—Twomey; Assembly Int. No. 1314—Streit, would amend the Education Law relative to payment of certain monies into state treasury so as to postpone until July 1, 1935 time when act shall take effect. Referred to the Finance Committee. Last year the Education Law was amended so as to have all monies collected as fees and fines from the enforcement of the various professional laws, paid directly into the state treasury and the Department of Education authorized to prepare, annually, a budget to cover all of these activities. It is now found impracticable to put that law into effect immediately and this bill provides a postponement for two years.

Senate Int. No. 1006—H. L. O'Brien; Assembly Int. No. 1247—Monahan, amends the Penal Law relative to poisoning or attempting to poison dogs or other domestic animals. Referred to the Codes Committee. The law now provides a penalty for persons convicted of poisoning horses, mules, or cattle. This amendment includes dogs. It did not originate with the antivivisectionists and has no bearing whatever upon vivisection.

It was probably inspired by the report of the poisoning of thirteen valuable dogs in New Jersey a few weeks ago.

Assembly Int. No. 1150—Schwartz, adds new section to the Penal Law making it a misdemeanor to sell drugs, medicines and other pharmaceutical preparations including lotions not having affixed on bottle, box, vessel or package a label giving name and quantity of each ingredient. Referred to the Codes Committee.

Assembly Int. No. 1152—W. F. Smith, would amend the Penal Law to prohibit solicitation of employment by or in behalf of an attorney. Referred to the Codes Committee. This is an other "ambulance chasing" bill applicable to lawyers, but it is so rigidly written that it unight be considered a crime for a physician to advise with his patient regarding the employment of an attorney, even when the patient and physician are the closest friends. If any of our readers not receiving this bill would like to study it, we shall be glad to send copies upon request.

Assembly Int. No. 1319—Averill, amends the Health Law by providing birth certificates shall be

filed with registrar of district of which mother of child is a resident, and where birth occurs in district other than that in which the mother is a resident, duplicate certificates shall be made out, one to be filed in each district. Referred to the Health Committee.

Assembly Int. No. 1322—Cuvillier, establishing a system of compulsory insurance to furnish benefits for employees in case of old age, unemployment, death, sickness and accident not covered by workmen's compensation and for their dependents, and to furnish maternity benefits, etc., a health insurance commission being created and \$200,000 appropriated. Mr. Cuvillier reintroduces his health insurance bill of many previous years. Last year the session was too short for Mr. Cuvillier to reach the bottom of his barrel of bills, but this year he has resurrected it. You will observe that it carries an appropriation of \$200,-000 and has been referred to the Committee on Ways and Means.

At our meeting on Thursday, February 16th, we took action on the following bills as indicated:

Senate	Assembly		no ao majamo
Int. No. 119-Mandelbaum	Int. No. 70—Canney	State fund	Disapproved

The committee recommends that the hospital lien bills be modified to include physicians and, if so amended, they are ready to urge the enactment

of either of the two bills now pending.

The special committee appointed by Governor Roosevelt made a study of medical and hospital problems in connection with the Workmen's Compensation Act and submitted its report to the Governor just before the close of his term of office. Governor Lehman the other day announced the appointment of a committee to review this report. The personnel of the committee follows:

Representatives of the New York Academy of

Medicine:

March 1-

Dr. Eugene H. Pool, New York City;

Dr. Frederick W. Bancroft, New York City;

Dr. George Baehr, New York City;

Dr. Adrian V. S. Lambert, New York City; Dr. Charles A. McKendree, New York City. Representatives of the Medical Society of the

State of New York:

Dr. David J. Kaliski, New York City;

Dr. Thomas McGoldrick, Brooklyn;

Dr. F. M. Miller, Sr., Utica; Dr. Harry R. Trick, Buffalo;

Dr. Frederick S. Wetherell, Syracuse.

The Temporary Emergency Relief Administration (T.E.R.A.), which has the responsibility of administering the state's relief with the thirty million dollars voted at the last election and recently supplemented by six million dollars from the federal government to be spent in the month of February, has made studies of the character of medical care administered in a number of communities up-state. It is stated that the surveyors reported medical care to be inadequate in many communities, and acting upon their reports, the T.E.R.A. has asked Commissioner Parran to be their medical advisor and he has designated Dr. Davis, of his staff, as his representative on the board. The Commissioner has asked Dr. Hyde to appoint a committee from the State Society to cooperate with him in formulating a program for improving conditions.

The Department of Health is cooperating with the T.E.R.A. in another way. Registered nurses engaged in case work, it is reported, made application to the T.E.R.A. for relief. Many of them are without work and it was suggested that they might be employed to work among those persons who are receiving either work relief or home During the last week the Commissioner has announced that a number of nurses have been appointed to work under the Department of Health, but more directly under such local agencies as there may be in accordance with this program. This is a temporary employment and may be discontinued at the close of this month, unless the committee feels their appropriation adequate to continue the work. These nurses are not employed to do public health work but family case work. This activity bears a close relationship to the administration of the Public Welfare Act to which we referred in our last bulletin. It would be well for each County Society to look into the matter of how that law is administered and how it is being supplemented by funds from the T.E.R.A., bearing in mind that the T.E.R.A. fund is an emergency fund and activities based upon it should be temporary in character and every effort should be made to keep them from developing a permanent aspect.

> HARRY ARANOW, Chairman, Committee on Legislation.

PUBLIC RELATIONS OF THE MEDICAL SOCIETY OF THE COUNTY OF MONROE

Editorial Introduction -- County Medical Societies are expending their activities to such an extent that the larger ones employ executive secretaries; while the smaller ones find it desirable to utilize the facilities of the County Tuberculosis Associations, thereby evolving a practical cooperation between the professional and the lay groups engaged in public health work

The executive secretary of the Tuberculosis and Health Association of Monroe County, Mr Raymond H Greenman, is also the executive secretary of the Public Health Committee and other standing Committees of the Medical Society of the County of Monroe. His account of the "Participation of the Medical Profession in Health Education," was presented before the American Public Health Association on October 27, 1932. The following abstract of that address is given with the approval of the officers of the Monroe County Medical Society.

Origin of Organized Activities:—Prior to 1929. the Medical Society of the County of Monroe, as a recognized entity, was practically unknown outside the profession. At that time, physicians were almost solely concerned with meeting the sickness needs of individuals. They were serving as "emergency" men rather than counselors. They had not yet become conscious of the fact that in the field of personal preventive medicine, i.e., dealing with non-contagious diseases, the private practicing physicians are in a field peculiarly, uniquely and exclusively their own.

The dawn of a new era in Rochester may be said to have begun in January 1930, with the enlargement of the membership of the Public Health Committee, the creation of nine standing sub-committees, and the undertaking of a study of the work of the hospitals and health agencies of the City. Eighty-eight different physicians served as members of the different sub-committees. These sub-committees rendered service in the fields of personal hygiene, nutrition, child hygiene, social hygiene, mental hygiene, prenatal care, tuberculosis and diphtheria prevention, and in community efforts to control cancer, heart disease and communicable diseases. A Committee on Periodic Health Examination was created to develop a program for the information of the profession and the general public.

Results of Medical Leadership:—The Medical Society of the County of Monroe is making a successful pioneer effort which has the approval of citizens of the community and the support of the membership of the Society. The health education program has been planned as a permanent activity of the Society. No longer is the leadership in medical public problems, which properly belongs to the organized medical profession, assumed by others; and no longer in Rochester do the official and voluntary health agencies have to undertake without needed support, the entire burden of educating the public in the principles of healthful liv-The individual physician is seeing, and will increasingly see, the benefit of organized and coordinated community effort and the establishment of harmonious working relationships. Participation in a community effort to give needed health education to the public is one of the opportunities and privileges of membership in a County Medical Society. The response of the physicians of Monroe County in public health projects is shown in Table One.

Table 3: Grouping of the Specialists in Monroc County, 1932

An effort has been made to make available to every member of the Medical Society up-to-date information and approved health education material. It was felt that physicians in general practice giving private instruction to their patients, have been, and will continue to be, the most important group of health teachers in any community. An effort has been made to enlist as many as possible of the members of the Society in a program of popular health instruction, i.e., informal adult education. The purpose of this instruction has been to arouse, stimulate and guide individuals to more healthful living, and to build up a feeling in the community of good will toward the organized medical profession.

In May, 1930, the opportunity to secure a regular fifteen minute sustaining period to undertake a radio broadcast program was provided by Stromberg-Carlson Station WHAM. Since that time the Sunday evening health talks of the Medical Society of the County of Monroe have been the most popular and successful feature of the Station's educational service. In the 110 broadeasts, 134 different private practicing physicians, eight public health officials and hospital superintendents, and three University Medical School Professors have participated. The worthwhileness of this effort is beyond question. More than 30,000 persons have received copies of the talks, as requested. Two hundred loose-leaf booklets containing the series of talks arranged by years have been sold to subscribers, including the Public Library, University, Schools, and practicing physicians and dentists.

In October, 1931, the Medical Society of the County of Monroe established headquarters in the Rochester Academy of Medicine Building and opened a Health Information Bureau. This Burean has been called on to answer many inquiries.

The initiation of the program was made possible by an appropriation made by the membership of \$600 from the capital fund of the Society, supplementing the service rendered without charge by the Tuberculosis and Health Association. In 1931, the County Medical Society shared in the cost of the extent of approximately \$1,900; and during the present year to the extent of approxi-

mately \$2,400.

Special credit was given for excellent use made of newspapers, pamphlets, motion pictures, lectures and radio talks as mediums of health education by the Medical Society of the County of Monroe, with the cooperation of the Tuberculosis and Health Association and the Chamber of Com-These activities were of essential service in making it possible for Rochester to win first place in cities between 250,000 and 500,000 population, after having been an honor city for two years in the Inter-Chamber Health Conservation Contest.

DUTCHESS-PUTNAM

The regular meeting of the Dutchess-Putnam Medical Society was field Wednesday, February 8, 1933, at the Chimney Corner, Poughkeepsie, N. Y. The neeting was called to order by the President, Dr. Samuel E. Appel, at 9:00 P.M.

The following candidates were elected to membership: Dr. Peter Montbello, Fishkill, N. Y., Dr. Norman T. Crane, Poughkeepsie, N. Y., Dr. Wesley G. Simmons, Dover Plains, N. Y. (trans-

ferred from Kings County).

A committee with Dr. W. A. Krieger, Chairman, was appointed to tender a dinner to Dr. Charles E. Lane, of Poughkeepsie, who has com-

pleted fifty years of medical practice.

The President announced the chairmen of the following committees: Public Health and Public Relations, Dr. Aaron Sobel; Legislative, Dr. C. Knight Deyo; Library, Dr. A. L. Peckham; Cancer, Dr. H. L. Palliser; Economics, Dr. J. T. Harrington.

Scientific Program

"Compensation Agreement," by Dr. Morris Rosenthal, Director of the Bureau of Compensation Arbitration, Medical Society of the County of New York.

Discussion by Doctors Lane, Harrington, Stein-

hardt, Krieger, and Sadlier.

"United to Help Each Other," by Dr. Irving D. Steinhardt, Treasurer, New York Physicians' Mutual Aid Association.

The meeting adjourned at 11:00 P.M. for refresiments. Present: Drs. Ashley, Cavanaugh, Lynn, Appel, Carpenter, C. E. Lane, Krieger, Sadlier, Rogers, Leonidoff, Rivenburgh, Stoller, Simon, Davison, Crane, Rosenberg, Harrington, G. E. Lane, Marks, Cadwell, Sobel, Morris Rosenthal, Steinhardt, Gosse, Price, Deyo, Thomson and Cotter (29).

II. P. CARPENTER, Secretary.

LIVINGSTON COUNTY

A regular meeting of the Livingston County Medical Society was held at the Old Madrid restaurant at Dansville, N. Y., on Tuesday evening, January 10th, 1933, at 6:30 p.m.

After a steak dinner the scientific program

was ably rendered.

Dr. H. E. Pearse of Rochester, N. Y., discussed "Neoplasms, Their Diagnosis and Treatment," accompanying his talk with lantern slides.

Dr. MacNaughton Wilkinson of Rochester, spoke on the "Use of Sodium Amytal in Obstetrics." He compared its qualities with that of Gwathmey's rectal ether anesthesia, and the so-called twilight sleep.

At the business meeting a schedule of medical economics was read by the secretary. After much discussion, this paper was referred to a committee of two appointed by the president.

There was a discussion relative to welfare medical care in Mt. Morris by several physicians.

George M. Doolittle, Secretary.

OUR NEIGHBORS

COMMITTEE ON THE COSTS OF MEDICAL CARE

The State Medical Journals have carried extensive comments on the Report of the Committee on the Costs of Medical Care ever since the report was made public on November 29, 1932. These comments have run the gamut from the severely critical to the mildly commendatory.

Critical Opinion from Illinois.—One of the more denunciatory criticisms is that contained in the Illinois Medical Journal of January which devotes a seven-page editorial to the subject, in which it says:

"From one end of the United States to another comes echo of unfavorable opinion of this thoroughly un-American report. The socialization of medicine does not set so well on the stomachs of those by whom this dose of sovietism was destined to be swallowed.

"There is scornful protest at the expressed hope of Dr. Ray Layman Wilbur that this Committee on the Costs of Medical Care might be propagated and that 'a continuing organization may immediately be formed to promote experimentation and demonstrations in local communities.'

"Now, Morris Llewellyn Cooke, an organization engineer, declares that we have come to a point where, if we are to survive, we must accept the contributions of science and engineering. Which is very fine coming from an engineer, but what has engineering got to do with the practice of medicine?—a lot of machine chicanery, economic jobbery, and socialistic tomfoolery.

"There has been founded a new group to carry on propaganda for the socialization and sovietization of medicine in America. The name of this new committee is the 'American Committee on Medical Costs.'

"What results this new committee will obtain, are more obvious than problematical. Its members, though, should study the public palate and put out findings more sugar coated than those embodied in their previous effort, and which have evoked a storm of criticism, indignation, revolt, condemnation, denunciation and even ridicule by the general public, the saner economists, and the medical profession. Especially is the press, lay and scientific, up to its ears on the question.

"Some ninety per cent of the lay press is against this report. Newspaper comment on the report of the Committee on the Costs of Medical Care is so favorable to the side of the physician and of the minority report that once more faith is justified in the lay press as a national leader and guide.

"Probably if a straw vote could be polled the

country over it would be discovered that 95 per cent of the population is better satisfied with its relations 'as is' with the family physician than they are with their relations with landlords, merchants, clergymen or their offspring's educators.

"Well, they should be. The physician gives his services without hesitation and his is the last bill to be paid. And though the Committee on the Costs of Medical Care insists that it is out to see that 'the doctor gets his' with the lure of government pay for government bossed doctors (which is exactly what will happen if this socialized medicine runs rampant with a heavy tax in an already tax-ridden country) this insistence is nothing but 'swamp fire,' an irresponsible will-o-the-wisp to lead the more credulous of the medical profession into a frightful quagmire.

"Let it be repeated, that quality of service has always been the thing dearest to the heart of the ethical doctor. This proximity will continue despite the dangling of false ideals by apostles of the soviet.

"The medical profession of the United States—the real medical men who know about medicine and not committees of butchers, coal dealers and ribbon merchants, professional philanthropists, or busybodies—will continue as they have always done. They must fix their economic balance to survive; but the scale must be their own, not that of the laity."

Laudatory Opinions from Massachusetts.—The New England Journal of Medicine, whose editor Dr. Walter P. Bowers, was a member of the Committee on the Costs of Medical Care, was the first State Journal to comment on the Committee's Report, which was made public on November 29, 1932. This Journal of December first said:

"The United States is said to be the only country in the world in which a substantial group representing the professions concerned with medical care have united with a group of social scientists and members of the general public in a careful study of the problems and needs of the situation. The subject is one in which there will be divergence on some points, but there can hardly be any difference of opinion that the present situation in medical service is neither satisfactory to the public nor to the profession; that many trends in economic life and in the scientific progress of medicine itself compel substantial changes; and that changes will be more advantageous to all concerned if made as a result of deliberate, purposeful and cooperative action.

(Continued on page 348-Adv. xiv)

Effective Iodine Medication

RIODINE

(Astier)

Organic Assimilable

Iodine

with the Danger of Iodism Reduced to a Negligible Factor

The usefulness of iodine therapy is well established, but how to secure it without iodism has long been a problem. In a general sense, of course, iodine therapy is inseparable from Iodism, but barring idiosynerasies, the severity of the symptoms of iodism is directly proportional to the amont of iodine retained in the blood. This amount, in turn, depends upon the quantity administered.

In RIODINE (Astier), which is a 66% solution in oil of an iodized glyceric ether of ricinolcic acid, containing about 17% of iodine, the iodine is held in such a form as to pass through the stomach unchanged and

be split in and absorbed from the intestines. Consequently, it is held in the cells in a lipoid-soluble form and remains in the body for a considerable period of time, eliminating the necessity of frequent and large doses of iodine—the cause of iodism.

Riodinc (Astier) is of obvious advantage in cases where the continuons action of small amounts of lodinc is desired, such as Cardiorenal disturbances, Arteriosclerosis, Bronchial Asthma, Chronic Bronchitis, Pulmonary Emphysema, Ghronic Rheumatold Arthritis, Latent Syphilis, Lead Poisoning, Hypothyroidism, Simple Goire, Obesity.

Prolonged Antiseptic Action in the Urinary Tract

ARHEOL (Astier) In acute inflammation of the bladder, posterior urethra, and genito-urinary tract—where there is pain, tenesmus, and frequent urination—one of the best internal medication adjuvants is the active principle of sandalwood oil—santalol.

By charging the urine with santalol, the entire mucosa of the bladder and posterior urethra is constantly heing laved with a soothing, reducing, and antiseptic fluid.

This is exactly what takes place when you administer ARHEOL (Astier).

For Arheol (Astier) is the purified active principle of sandalwood oil, containing never less than 98% of santalol. It is free of the therapeutically inert but irritating substances found in ordinary sandalwood oil.

In the acute stage of Gonorrhea, Arbeol (Astier) alleviates pain, reduces inflammation, lessens involvement of the posterior urethra, diminishes the frequency of urination. When local treatment is indicated, it acts as a useful adjuvant to treatment with local antisepties and astringents. It may be used to advantage in Cystitis, Vesical Catarrh, Prostatitis, Porterior Urethritis. In Pyelitis and Pyelone-phritis, owing to its dependable urinary antiseptic properties, Arheol (Astier) is a definite aid in overcoming infection in the kidney and renal pelvis.

Chocolate Pudding

... at least that's what he thinks NEO-CULTOL is. Eagerly he takes his tri-daily treat of this delicious chocolate-flavored mineral oil jelly, and with each dose he gets a concentration of the healthful acidophilus bacilli.

NEO-CULTOL is equally effective with adults and offers a pleasant method of administering the *B. acidophilus*. The product furnishes a concentration of *bacillus acidophilus* in a chocolate-flavored mineral oil jelly medium. The medium also acts as a mild lubricant which in turn permits an easily passed fecal mass.

NEO-CULTOL will be found useful in the treatment of intestinal toxemia and its sequelae, constipation, mucous colitis, stasis, etc. It is an ethical product, never advertised to the public.

NEO-CULTOI

"An answer must be given to one important question and that is: Will organized medicine take its place in the solution of the problems now before this country respecting medical service to all the people?"

The New England Journal of December 8th says:

"The Committee may well feel satisfied with the work which has been carried on, and especially pleased with the many expressions of approval of its recommendations. A very significant feature of the minority report is that, in its dissenting opinions, modifying statements are given to the effect that there are possibilities of objectionable forms of group and contract practice and also that there is no opposition to the principle of insurance in dealing with the costs of illness, but only to those forms which are destructive of ethical medical practices.

"There is no real reason to believe that the foundations of the general practice of medicine and the close and intimate relations of the family doctor are to be torn asunder. The recommendations of the majority will supplement the work of the individual physician and provide for service not now available, or indifferently supplied, in many instances.

"There is sufficient evidence of support of the majority report by far-sighted physicians, so that there will not be any general reaction to catchword phrases designed to stampede the profession.

"The reports are now before the medical profession, sociologists and the people. In the last analysis, the people will decide many of these questions and a responsibility rests upon students of the problems to have recommendations passed upon by an intelligent jury."

The New England Journal of December 22nd says:

"The recommendations of the committee are not 'revolutionary.' On the contrary, it is possible that the committee has saved the American people from a change in the provision of medical care which might quite properly have been termed 'revolutionary.' Most countries in Europe and some in other parts of the world have adopted, during the past half century, systems of compulsory state illness insurance. Before the war, state insurance was proposed and considered in some eight or ten commonwealths in the United States and much public sentiment had developed in its favor. If the war had not come, the protagonists of this system of medicine would probably have become increasingly active in urging its consideration and some of the states might have adopted it before now.

"Those who read the report may trust its framers to interpret it. It will be seen that the importance of the personal relation between the patient and practitioner is recognized and repeatedly em-

phasized. The recommendations of the main report definitely provide for its preservation. The report safeguards many other essential interests of both physician and patient. The committee has done its work thoroughly and given due consideration to these matters.

"That there should be honest dissent from the findings of the Committee is desirable, but it is reasonable to expect that bitter recrimination will not be the resource of the objector. There should be no personal quarrel in the medical family."

A Stimulation to Action in Indiana.—The February number of the Journal of the Indiana State Medical Association, discusses the reaction to the report as follows:

"As was to be expected, organized medicine opposed the recommendations of the majority of the committee. It was patent that we could not carry on under the proposed plan without sacrificing much of the progress we have made in recent years; and many of our lay friends, now that our side of the question has been explained to them, are strongly impressed with the fact that the recommendations cannot be carried out without jeopardizing our professional future.

"The committee has, however, rendered a valuable service to the profession; it has brought us to a stern realization that we have been fast asleep for many years; that our very existence has been and is being threatened, and that we have calmly sat by while this sort of thing was going on. In fact, we are many years late in realizing that sapping has been going on right under our very foundations. Just what we can do about it remains to be seen, but certain it is that we have our work

cut out for us.

"One of our greatest shortcomings is that we are slow in taking the laity into our confidence: for generations our profession has been shrouded in at least some degree of mystery. It is only in recent years that we have made any effort to publicize our achievements, to speak of the things we are trying to accomplish. True it is that some of our state associations are doing a most commendable work—Indiana is a leader in this field—through the very creditable work of its Bureau of Publicity. But even more active measures will have to be instituted to overcome the effect of the

"All of this convinces us that if we are to scotch the snake of state medicine and the paternalistic tendencies of our government we will have to quit this pussy-footing and get down to brass tacks. This is true not only of our state association but of the parent organization as well. The county society and the individual members of the profession have their work cut out for them. We have talked a lot; we have resoluted and resolved; we have admitted that something must be done

publicity given the committee report.

about it; but we have accomplished very little in (Continued on page 351—adv. xvii)

(Continued from page 350-adv. xvi)

comparison to the publicity attending the release of the final report of the committee.

"We have always maintained that we can and will have the support of the public in any of our worthy undertakings. This has been proved on so many occasions that it is almost axiomatic. No one can make better contacts than the individual physician because of his personal relations with his patients, many of whom will be very glad to render assistance in such matters as the case in hand. We should not enter into a long-winded discussion of medical conomics with all of our patients, but all of us have frequent opportunity to talk things over with thinking people,

The Data Valuable to lowa .- The January number of the Journal of the Iowa State Medical Society has the following editorial on the Report:

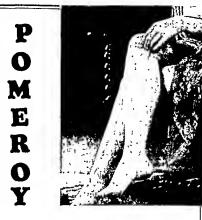

"Medicine has been developed as a profession upon a basis of medical ethics; ethics which demand a personal and intimate, confidential contact between physician and patient. The medical practitioner, busy with the exacting duties of his profession, has rarely paused to give consideration to the methods of mechanical efficiency of 'big business.' He has long been keenly alert to the problems concerned in rendering a better and more efficient service and his studies have been directed in these channels. He has been interested in the quality of professional service rather than the cheapness with which this service could be dispensed.

"Disturbed by the apparent high costs of medical care, a committee, unofficial in character, came into existence some five or six years ago to investigate this problem. In many ways the activity of this committee appears unfortunate. In its inception, the committee openly stressed the alleged high costs of medical care and thereby directed attention to the costs of illness in an unfair light; and in its conclusion recommended a plan for the socialization of medical care inimicable to the welfare of the medical profession. In spite of these facts, the tremendous amount of data accumulated by the committee in its five years of research has served a highly useful purpose in causing the attention of the profession to be focused on the cconomic aspects of medical practice."

Paternalism Deplored in Ohio.—The Ohio State Medical Journal for February criticizes the report of the Committee on the Costs of Medical Care in the following editorial:

"To those wishing to know what some of the leaders in industry and business think about the recently issued report of the Committee on the Costs of Medical Care, we recommend the following comment on the subject by Merle Thorpe, editor of Nation's Business, official publication of the Chamber of Commerce of the United States, and

one of the best informed authorities of the day on social, economic, governmental and political trends and developments.

"Writing in the January, 1933, issue of Nation's Business, Mr. Thorpe declared:

- "'It is a thankless task to criticize the labors of the Committee on the Costs of Medical Care headed by Secretary-Doctor Wilbur of the Department of Interior.
- "'The descent into paternalism and from paternalism into socialism to easy—and doubly easy when the way is greased by sentiment, by the desire to better the health of the community, by sympathy for suffering, by the knowledge that costs of medical care fall with crushing effect on the overalled and white collared poor.
- "'The Committee would have medical service provided largely by "organized groups" an extension of the already increasing method of practice through clinics.
 - "'How pay for this group service?
 - "'Here's part of the Committee's recommendaons:
- "1. Voluntary cooperative health insurance, in which organized groups of consumers unite in

- paying into a common fund agreed annual sums, in weekly or monthly installments. . . .
- "'2. Required health insurance for low-income groups. . . .
- "'3. Aid by local governments for health insurance. Part of the people, because of their low income, cannot pay, even on a periodic basis, the full cost of complete service in cases where the community relies for the provision of medical service primarily upon the purchase by its people of voluntary health insurance. Such communities may well use tax funds to the extent necessary to supplement the payments of these low-income families. When health insurance is required by law, it may also be necessary and desirable that a contribution be made from government funds.
- "'The socialism of medicine is but a step toward the socialism of industry.
- "'To tax A to pay B's doctor's bill is an appealing plan particularly when we put in on the ground of conserving public health.
- "'But why not then tax A to pay B's food bill since it is nutrition that is essential to health?
- "'It is comforting to know that the doctors themselves are in revolt at the Wilbur report'

"It might well be added that it is interesting to doctors to know that those in other professional and business pursuits do not find the majority report of the Committee on the Costs of Medical Care wholly acceptable."

Judicial Attitude af Nebraska.—The Nebraska State Medical Jaurnal for January is judicial in its attitude towards the report of the Committee on the Costs of Medical Care, as is shown by the following editorial:

"Our first reaction to the report was that it would exert a tremendous influence in favor of state medicine; mature later reflection has modified this considerably. Few physicians are in favor of state medicine as found in European countries. Most physicians see the need of some better method of caring for the poor and the white collar class. We believe, with others, that few people suffer from actual want of medical care under the prevailing system. Rarely does radicalism prevail: it does call sharp attention to problems that cry for solution. Is it not possible that out of this study and from the recommendations made may develop a policy entirely wholesome to the profession and the laity?"

The Humanities in Medical Practice in Alabama.-The January issue of the Jaurnal of the

Medical Association of Allabama, discussing the medical needs disclosed by the report of the Committee on the Costs of Medical Care, says, editorially:

"This battle is sure to wage fiercest around the humanities, the traditions and ethics of our profession, which are as intangible and unstandardizable as love. Little as the public may realize, these are values which cannot be permitted to perish. Organized medicine today-yes, organized primarily for scientific pursuits, but not for economic struggle-finds itself steeped in a seething vat of commercialism with many forces seeking to absorb and appropriate it. The commodity which medicine alone possesses must be dispensed in a manner which will be both satisfactory to the people at large and acceptable to organized medicine—its dispensers. This means that the medical profession, speaking through its national, state and local organizations, must furnish the requisite leadership and shape the policies."

Uncertainty in Florida.-The January issue of the Jaurnal of the Florida Medical Association. Inc., takes a neutral attitude toward the report of the Committee on the Costs of Medical Care, as is shown by the following editorial:

"Even Einstein cannot explain his theory so

they can understand it. This is much the status of the Committee on the Cost of Medical Care and its findings. We have the report and we also have writings everywhere, both doctors and laymen commenting on and explaining it, and many whether they know of its provisions or not. However, the Committee itself cannot tell how the report should be interpreted nor what the results of an attempted adoption would be. In a very blasé way the majority report states that 'a continuing organization may be formed to carry on experiments,' to see if their theory will work.

"We are constrained to believe that the best interest of medicine, and the public, will be served by pigeon-holing the whole report. We further are constrained to believe that each community should take care of its own medical indigent by the organization of a full-time county health unit, which the Florida Legislature has already authorized. Each unit should employ enough physicians to handle all indigent sick; indigency being determined by a welfare investigating group. If a county or city hospital exists, those needing hospitalization can well be taken care of, but when no county hospital is available, those needing hospitalization should be cared for in private institutions at a substantial, patient per diem rate."

FULL-TIME SECRETARY IN KANSAS

The employment of a full-time secretary by State Medical Societies was discussed in the Journal of the Kansas Medical Society of August, 1932, and abstracted in the New York STATE JOURNAL OF MEDICINE of December 1, 1932. The Kansas Journal of January continues the discussion as follows:

"The most recent information available in the Journal office is that seventeen state medical societies employ full-time secretaries. Sixteen of these states were listed in a previous discussion on the subject. Virginia, the seventeenth state, employs a lay sccretary.

"The average yearly salary received by fifteen of the seventeen sccrctaries is \$5,450.

"California was the first society to employ a full-time secretary, nearly thirty years ago; the most recent, Maine, approximately three and onehalf years ago.

"The 1932 dues for the seventeen societies averaged \$10.50. Prior to employment of a full-time secretary, the average annual dues of eleven of the societies was \$6.35. The average membership of the seventeen societies was 2,562. Colorado, Maine, Oregon and West Virginia, each have a lesser number of members than Kansas. Dues for the year 1932 for the four societies

(Continued on page 355-adv. xxi)

(Continued from page 354-adv. xx)

were: Colorado, \$10.00; Maine, \$8.00; Oregon,

\$20.00, and West Virginia, \$10 00.

"As stated in the previous discussion, the proposed plan of employing a full-time secretary was not in any way a reflection on the ahility or the work of the officers of the society. Any organization which employs a full-time official has the entire time of that official devoted to the interests of that particular organization.

"There are sufficient reasons why a full-time executive secretary should be employed. However, if such system is adopted by the society, it will undoubtedly result in an increase in the annual dues. Due to the economic depression, an increase in dues is not justified; the result probably would be a decrease in membership in proportion to the increase in dues. It has been suggested the Journal could be made a source of revenue for this purpose. More advertising could be secured for the Journal; however, with the publications of other state societies, the Kansas Medical Journal has made a policy of accepting only Council approved advertising. It is not believed the members wish to throw the columns open to indiscriminate advertising.

"The committee appointed at the annual meeting to make recommendations after a thorough investigation of the question includes: J. F. Gsell, Wichita; C. C. Nesselrode, Kansas City; Walter Stephenson, Norton; A. R. Chambers, Iola, and Milton B. Miller, Topeka.

"The committee report will be made at the midwinter meeting of the Council in Kansas City, January 17."

PHILIPPINE JOURNAL

The Journal of the Philippine Islands Medical Association was founded in 1921. The editor, Dr. A. S. Fernando, writing in the December issue, makes his annual report as follows:

"The position of Secretary-Treasurer and Editor were merged in order to effect a decrease in the expenses of publication of the Journal, but without decreasing the number of its pages. In spite of his lack of experience in editorship, the Secretary-Treasurer had to obey this mandate of the house—the governing body of the Association.

"In order to make the Journal a real official organ of the Association and to give the readers more information regarding medical matters and activities, there have been created or revived the following special departments which appear regularly in every issue: Current Medical Literature (Philippines); Society Activities; and News Items, covering medico-social and personal matters of interest and the like. Occasionally reports of the Board of Medical Examiners and those pertaining to medical legislation were published. "From January to November 30, 1932, the

Journal provided 596 pages of reading matter (Continued on page 356—adv. xxii)

MALNUTRITION

-especially in children who dislike milk

White malnutration in children may be due to premature birth, to some constitutional debility or the development of some serious disease, the grent majority of cases are due to improper or faulty diet.

Insufficient milk is by far the most serious failing in children's deets. This is due, no doubt, to the fact that so many youngsters dislike milk and refuse to drink it. More and more physicians are meeting this problem by prescribing Cocomalt—which is as alluring as chocolate soda to children.

Prepared as directed, Cocomalt adds 110 extra calories to a cup or glass of milk—increasing the protein content 48%, the carbohy drate content 184%, the mineral content (calcium and phosphorus) 48%. It is rich in Vitamin D, contaming no less than 30 Steenbock (300 ADMA) units of Vitamin D per ounce—the amount used to make one cup or glass.

This rich Vitaniin D content, combined with the extra calcium and phosphorus which Coconalt provides, aids substantially in the development of strong hones and teeth.

Cocomalt comes in powder form only—at grocers and drug stores—in ½-lb, and 1-lb, cans. Also in 5-lb, cans fur hospital use, at a special price. R. B. Davis Co., Hoboken, N. J.

HYNSON, WESTCOTT & DUNNING, Inc. Baltimore, Maryland

(Continued from page 355-adv. xxi)

(excluding the advertising pages) and 64 pages of the proceedings, making a total of 660 pages. The number of pages for the corresponding period last year was 456, showing an increase for 1932 of 204 pages.

"Number of copies printed, 13,576, as against 12,813 for last year.

"During the same period 21 editorials appeared, as compared with 13 of last year. To the credit of the Journal, the editor has succeeded in encouraging the associate editors to contribute regularly to the editorial columns on diversified subject matter, thus presenting a good cross-section of the views of those who stand high in the medical profession of our community. This section, in fulfilling its function, has faithfully tried to reflect the highest ideals and aspirations of the medical profession within the territory the Journal serves.

"The quality, the world-wide distribution, and the increasing number of our exchanges seem to show that our Journal is fast forging ahead. A few manuscripts from foreign authors connected with well-known institutions have been received for exclusive publication in our Journal; these will appear in the near future."

SOCIAL TRENDS IN DELAWARE

The January issue of the Delaware State Medical Journal contains an editorial on social trends which begins with the subject of technocracy, and ends in a spirit of optimism as follows:

"To corroborate our own viewpoint, now comes the report of President Hoover's Research Committee on Social Trends, just released after a careful and painstaking study of three years. No report in recent years seems founded on better facts, or steeped with more common sense. The full report, which is the work of over 500 investigators, fills two volumes of 1508 pages, and is supplemented by 13 monographs. As pertains to the medical profession and public health, it states, primarily, that medical organization has not changed as rapidly as scientific medical research, that there is an uneven distribution of physicians, comparing rural with urban populations, with accompanying hardships to both people and profession; and that the total cost of medical care (of which the doctor receives only 30 per cent) is perhaps not too high, and totals approximately \$3,500,000,000 a year.

"This report, which is strictly fact-finding and contains no specific recommendations, bares the facts that our life has became disjointed and upset because the flow of credit is not synchronized with the flow of production; that machines are dislocating labor; that we devote far more atten-

(Continued on page 357-adv. xxiii)

(Continued from page 356-adv. xxii)

tion to making money than to spending it; and that the church and family have declined in social significance; and yet, in the midst of this terrific indictment against the national trends at large, the medical profession is, relatively, given a very clean bill of health.

"We thank God for these few kind words; they will go far towards ameliorating the hurt inflicted by recent previous reports, the chief connotation of which has been that medicine has become somewhat backward profession, almost devoid of social interest and advancement. On the contrary, we maintain the thesis that the medical profes-

sion has more than kept its place in the march of modern civilization, and that, further, more than any other group in our midst, it has projected itself into the future, and provided that vision without which, according to Holy Writ, the people shall perish.

"In conclusion, rating one report against another, balancing charges of collective insufficiency against collective proficiency; and comparing medical individualism with medical socialism, let

this be our slogan:

"The American medical profession will be sovietized only if and when it permits itself to be sovietized."

PACKAGE LIBRARY SERVICE IN TEXAS

The January issue of the Texas State Journal of Medicine describes the library service of the State Medical Association editorially, as follows:

"The Library now contains 3,703 volumes. One hundred and twenty-nine medical journals are received monthly (some are published bi-monthly and others weekly). Twenty-nine thousand, five hundred and forty reprints have been accumulated and are on file, indexed in accordance with the

subject index of the Quarterly Cumulative Index Medicus. These reprints are being continuously gathered at a rate of from 500 to 1,000 each month.

"While the package library service has perhaps a fairly good record for the approximate thirteen months of its existence, it is by no means being utilized as it should be. It is believed that despite

"The service has been used by the profession in almost every section of the state and the distance from the central office in Fort Worth has been of no consequence. Fifty-four counties and sixty cities have used the service. A total of 134 packages, containing 1,482 items, have been mailed."

GENERAL HEALTH COUNCIL IN PENNSYLVANIA

The February issue of the Pennsylvania Medical Journal contains a paper read before the twenty-eighth Annual Conference of Secretaries of the County Medical Societies of Pennsylvania, held in Harrisburg, December 6, 1932, by Lester H. Perry, Executive Secretary of the Medical Society of the County of Allegheny, in which the city of Pittsburgh is located. Mr. Perry describes the General Health Council of the County as follows:

"I have mentioned the General Health Council. This organization is separate and distinct from the Allegheny County Medical Society. It has been sponsored and nurtured for some time, however, by our Public Relations Committee. I should like at this time to discuss the reasons for such a liaison.

"The primary purpose of the General Health Council is to serve in a coordinating and planning capacity. Efficacy of the service rendered and economy of the operation of such are the benefits which accrue to the community when health efforts are carefully planned and properly coordinated. In any community in which several health groups are working independently, there are likely to be found those that are worthy and efficiently conducted, those that are useful but extravagant, and those that are both ineffectual and mismanaged. Often there is a group of pretenders who, for selfish or other personal reasons, are antagonistic to every sound health program which is proposed. The idea of the Health Coun-

cil is to aid in bringing about an adjustment of efforts among the legitimate forces and to help the community see the pseudo-health groups in their proper light.

"The Council is an organization formed jointly by organized medicine, individual physicians, lay representatives of health agencies, and other interested persons to serve in a planning, coordinat-

ing, and supervisory capacity.

"Here the community funding organization (by whatever name it is known—the Community Chest, the Welfare Fund, or some other) assume the financial responsibility, interested lay person cooperate in carrying on the activities, and physicians furnish the proper medical leadership This arrangement is almost ideal.

"For that reason, the Allegheny County Medi cal Society assumed the leadership in the re organization of the General Health Council and in its operation thus far they have maintained that leadership. Moreover, they are determined to surmount certain existing difficulties and se cure for the General Health Council proper rec ognition in the community. When these funda mental problems are solved, however, the worl will not be finished. In fact, it will never be finished, for as soon as the medical profession fails to direct the affairs of the General Health Council, then some other group will do so. Con sequently, the manifestation of active medica leadership in the administration of such a counci must continue indefinitely.'

NEW YORK POST-GRADUATE MEDICAL SCHOOL

SIX WEEKS' CLINICAL CONFERENCE IN

OTO-LARYNGOLOGY

March 13 to April 25, 1933

The sessions are to be somewhat in the nature of a round table conference, stressing the modern methods of diagnosis and treatment. There will be four sessions a week, beginning at 4 P.M. on Monday, Tuesday, Thursday and Friday. Each session will last about one hour. General practitioners, as well as those concentrating on this special branch of medicine, will find ample opportunity to keep pace with the most recent developments. For further information, address

THE DIRECTOR.

302 EAST 20th STREET, NEW YORK CITY

ADVERTISING IN THE TEXAS JOURNAL

The Texas State Journal of Medicine for February contains the following appeal for the pro-

motion of its advertising pages —

"This editorial will be short and, we hope, sweet It should be read by every member of the State Medical Association—If this is done, and a fair proportion of the readers will act accordingly, it will mean much to the success of the Journal and, consequently, to its standing as a first-rate publication

"Last year at this time the Journal carried the equivalent of 49 pages of paid advertising. This immber carries the equivalent of 39 pages, a loss of 10 pages. That means that we are out \$250 00, and must cut down our reading pages that much—or, to be more accurate, that much less the actual cost of printing. Or, to make it plainer still, if we had the same number of advertising pages we had last year we could without loss add

eight or ten more pages to this number

"Of course, it is very largely the depression, but we must not hastily conclude that it is entirely As a matter of fact, quite a few of our potential advertisers concerns which ordinarily do everything in their power to support organized, scientific medicine, are seeking their publicity and putting out their advertising propaganda in such a way as to short circuit those institutions which are doing all they can to increase the value of scientific medicine to its dependent public by the constant reeducation of the medical profession This will be clear to our readers if they will stop to consider how many of those concerns are now advertising by radio, by house organs, so called. by mail, and through the preparation of moving picture films, charts, and the like These may all be perfectly legitimate and proper from an ethical standpoint, and we can find no fault with them except that the results thus obtained could be as easily obtained through the Journal

"We might make the same complaint as relates to the technical exhibits at our annual session

"What can we do about it?

"Just this. There is hardly a member of our Association but who can exert some influence with some advertiser. He should exert that influence whether the advertiser is at the present time ad vertising with us, never has advertised with us. or has recently quit Detail men are quick to carry the news back home when there is criticism of their people. If our advertisers had all of the business our members are giving to non advertisers, we are sure the story would be a different one It would be different if our advertisers even suspected that our members were directly interested in their respective enterprises, and because of their cooperative status. This isn't a job for 'George' to do It is one that our members individually must attend to Do it now!"

THE INDIGENT IN INDIANA

The February issue of the Journal of the Indiana State Medical Association describes the following plan for the care of the indigent in Lake County:

"The proposal of the Lake County Medical Association to divorce the care of township indigent patients from the blighting influence of politics is the most sensible that has been advanced thus far.

"According to the association's plan a rotating committee of three reputable physicians would be elected for alternate terms of three months with virtual control over township medical aid.

"This committee would permit family physicians to treat indigents whenever possible. It also would study each case, diagnose the treatment if necessary, and then allot payment to the attending physicians from a stipulated monthly total on the basis of an ingenious, but thoroughly practical, point system.

"Under this scheme, the township trustee and the township advisory board would exercise only supervisory power. The county commissioners, too, would be relieved of the necessity to scan each medical claim.

"Claims would be submitted to the commissioners by the committee only after they had been approved by a majority of the committee members."

"In other words, the township divisions of the Lake County Medical Association would supervise and control medical poor relief and not the trustee or the township advisory board. That would remove this phase of the trustee's duties from political control.

"We can think of no better plan than that. It certainly would be an improvement over the present method of doling out medical plums to physicians in conformance with the discredited 'spoils' system.

"Then, too, the Lake County Medical Association would be Diuresis is recommended in many forms of Heart Disease as an adjunct to other appropriate treatment.

EXAMINATION OF SCHOOL CHILDREN IN FLORIDA

The November issue of the Journal of the Florida Medical Association contains the following account of the attitude of two county medical societies toward the medical examination of school children:

"The doctors of Orlando and Orange County assembled in the lounge of the Orange General Hospital Wednesday evening, the 19th, for their regular October meeting, Dr. G. S. Osincup, president, in the chair.

"A letter from the Parent-Teachers' Asociation was received requesting the assistance of the doctors for their pre-school clinic This brought up much active discussion because of the stand taken by the County Society to discontinue taking any part in these hit and miss group examinations of school children. The doctors waste their time because the examinations are hasty and extremely superficial; very few of those being examined receive any benefit and the breasts of the P. T. A. members and the individual parents are filled with false security. Following much active discussion, in which probably every member took part, it was voted that the children be (1) advised by the Parent-Teachers' Association to go to their family physician and that (2) the examinations should be made at the office individually and not en masse; and that (3) a fee of \$2.00 should be demanded, this fee covering a complete physical examination of blood, urine, etc., or whatever may be deemed necessary. That, it was felt, would result in the individual getting a worthwhile examination and the doctors not subscribing to unscientific group examinations.

THE OCULAR FINDINGS IN RETROBULBAR NEURITIS*

By ARTHUR J. BEDELL, M.D., ALBANY, N. Y.

ETROBULBAR nenritis as we will discuss it refers to an inflammation of some part of the optic nerve between the globe and the optic foramen. DeSchweinitz appropriately called this "orbital optic neuritis" and as his term is both descriptive and expressive, it is to be preferred to retrobulbar

or retro-ocular neuritis.

My confreres in this symposium are to speak about causes, treatment and pathology, so my remarks will be limited to a review of the classical ocular symptoms, a resume of some illustrative cases and a word of caution in differentiating orbital optic neuritis from the diseases which simulate it. The symptoms on which the diagnosis is based are present in many conditions, therefore, the opinion of an expert ophthalmologist is necessary to establish the case.

Sudden loss of vision, a central scotoma, pain on motion of the eyeball and tenderness on globe pressure, a suggestive pupillary reaction and absence of early fundus changes are the usual manifestations. Later in the disease a questionable pallor of the disc particularly the temporal half may be found. One

or both eyes may be involved.

Loss of vision: Some observing individuals speak of dim sight, which is worse in a bright light, others refer to a haze and read with difficulty while most of our patients simply say they cannot see. The degree of central vision reduction ranges from mere hesitancy in reading 6/6 to blindness. The light sense is reduced,

There is always a central scotoma which varies in size as well as intensity from the relative to the absolute. This is often only de-tected by using small color targets to determine the partial or complete lack of response to red or green stimuli. A permanent central scotoma may persist even in the severe acute cases but it is more frequently a sign of the chronic form. It is interesting to observe that in the alcohol and tobacco cases the scotoma

*Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N Y, May 25, 1972

including the macula and the blind spot, caecocentral, is oval whereas in others it is more commonly found. The loss of vision is often transitory. Recovery of part or all the function is the rule but there are some in whom recurrences are common. These recidives are

very suggestive of multiple sclerosis.

Pain on motion of the eyeball and tenderness on pressure seem to be present in certain acute cases. In our experience few patients have referred to globe pain and only rarely has tenderness been noted. The reaction to pressure is so equivocal that I only have to remind you of the unreliability and uncertainty of the degree of response when you press on the floor of an infected frontal sinus or antrum. Few individuals seem capable of accurately weighing physical sensations when alarmed by the sudden discovery of poor sight. When present these symptoms are helpful in differentiating this disease from others.

Much may be recorded for and against the value of the pupillary signs in orbital optic neuritis. It is said that the light reaction is impaired and particularly that the first pupillary contraction in the amblyopic eye is normal but that the pupil fails to maintain this contraction under continued exposure to the same light. This is not limited to the disease under discussion. The explanation may lie in the size and character of the scotoma just as in hemiopia under certain conditions the pupil fails to react because no light reaches the active retina or in optic atrophy with extremely contracted field where the examiner neglects to reflect the light on to the functioning retina. A suggestion of disease is, therefore, elicited when we note the pupil action but to me it is of little or no diagnostic value.

There used to be an old expression which defined this disease as one in which neither the patient not the ophthalmologist saw anything. This is to a great extent true in practice if we limit our consideration to the acute disease. If, however, we include chronic retrobulbar neuritis, we often find a pathological pallor of the disc usually limited to the outer

half. The question of color of the nerve head is a daily source of discussion and surely a limited experience in ophthalmoscopy and variable illumination will reduce the value of the observer's findings on this point almost to the complete disregard of them.

Before concluding that we have an orbital optic neuritis we must be very certain that retinal, choroidal, cerebral and mental conditions capable of producing this symptom complex have been excluded. This is sometimes so extremely difficult and confusing that operations are performed and the patient subjected to prolonged periods of observation before the correct diagnosis is confirmed. Fundus changes with the exception of those in the disc, must be excluded. The examination must be made through dilated pupils with the most instruments. Minute retinal choroidal alterations in the macular region may simulate the disease we are discussing and certainly an inspection without dilatation of the pupil is to most of us absolutely unsatisfactory.

The essayists to follow me will stress the causative agents and they will, I am sure, go into the differential diagnosis of orbital optic neuritis from hysteria as well as retinal and choroidal inflammations. The role of multiple sclerosis, nasal sinus infections and the host of other etiological factors including hypertension will be explained by them.

Some illustrative cases are included so that the particular causative agent may be suggested in their clinical summary.

Multiple Sclerosis.—R. T., female, 26 years old, has never worn glasses. About two months ago she noticed that the print gradually became less distinct. She did not have any réal pain in her eyes but a rather dull frontal headache. About three months before this attack she complained of a cold and referred to pains in her legs, knees, wrists and ankles. There was, however, no redness of any of these parts.

Examination of the right eye, vision 1/200. The 3 mm. regular pupil reacted very sluggishly to light. The disc was clear and distinctly outlined with a definite pallor of the The retintal arteries were very temporal half. evidently contracted and the retinal veins were very slightly distended.

Left eye in all particulars similar to the right. Vision 2/200. There was a large irregularly ovoid central scotoma. The roentgenograms showed that the nasal accessory sinuses were all clear. There was no evidence of sclerosis in the bony wall or chronic thickening of the mucosa.

She has recovered all of her functions except sight. The disc is becoming paler but the scotoma does not change. The physical examinations have been essentially negative except those for the signs of multiple sclerosis.

Tobacco Alcohol Diabetes .- It may of interest to some of you to recall that the late Lee Francis of this city, Buffalo, published two papers dealing with retrobulbar neuritis in diabetes.

An interesting example is A. S., a male, 52 years old, who said that his vision had been hazy for fifteen months and that the sight of the left eye had been practically abolished for one year. For thirteen years he has had diabetes and for two months before his vision began to fail he was on insulin, ten units twice a day.

The vision of the right eye 20/30. Pupil was 2.5 mm. regular, active, media clear, disc There were a great many small, rounded, deep retinal hemorrhages, with perivascular streakings about both arteries and veins. The disc was pallid with a large central excavation. The field of vision was contracted but no scotomata are demonstrable.

Left eye vision 5/200. Pupil 2.5 m.m. regular and active. The disc was white, clearly and distinctly outlined. The veins were of normal caliber but the lumen of the arteries He had an oval central was irregular. scotoma.

This patient used both alcohol and tobacco excessively and had diabetes. The etiologic discussion is one of considerable interest, but in deference to the next essayist it will not be entered into at this time.

Allergy.—When the various manifestations of unstable sympathetic control are understood, we will probably appreciate cases like that of Miss G. S., 26 years old. One week before her first visit she noticed a blur before the right eye, which has steadily increased until things seemed black. Vision reduced to 20/70. The pupil was 3.5 mm. regular and active, the media was clear and the fundus negative. There was a scotoma especially wide to the upper, outer side. The left eye was without change. As she had had hay fever and was known to be allergic, ephedrine was used. She made a rapid, complete recovery.

When intra-orbital neuritis is found with an infected nose, the relation may or may not be that of cause and effect but nasal treatment is demanded. Such experiences are common and for that reason no example is included in this short presentation.

Alcohol.—Even now we see in the parched United States of America cases like E. R., a 42-year-old man, who, after a drinking bout, found that he was unable to see clearly. After spending three weeks in a sanitarium he came in for evanimation and we found that the vision of the right eye was 20/70 pupil 3 mm regular, active, media clear, disc distinctly and clearly outlined. Left eye vision 20/70, physically the same as the right except that the temporal half of the nerve head was pale. With considerable difficulty he was kept from his tobacco and alcohol and in four months there was a complete restoration of function

If we were to include as retrobulbar neuritis the large group of lesions in and about the sella, local arachnoiditis or frontal tumors, we would encounter much more difficulty in

differentiation

There is one peculiar form of retrobular neuritis which deserves special mention because of its familial characteristics. I refer to hereditary blindness or Leber's disease. A typical case will emphasize the seriousness of the condition and perhaps serve to stress the necessity of a careful family history.

Leber's Disease, Hereditary Optic Atrophy—When TG was 19 years old he awoke one morning to find that he could not read with his right eye and within three days lost the sight of his left. He had no pain, no tender-

ness on pressure or on globe motion and he exhibited no signs of localizing value. The appearance of his fundus fifteen years after onset shows the characteristic optic atrophy with vision reduced to 3/200 and a large central scotoma. He was the third generation of a family in which there were several cases of Leber's disease.

Every ophthalmologist has had experience with intraorbital optic neuritis and has observed the subsidence or disappearance of symptoms following the removal of common infecting foci. Therefore, no histories are appended to represent that large class

With ordinary skill and knowledge, the diagnosis of retrobulbar neuritis can be inade without delay but to determine and remove the cause by establishing appropriate treatment calls for a display of superior intelligence, judgment and experience. Always remember that most acute orbital optic neuritis tends to get well, so that your careful analytical investigations and recorded observations will do much to conserve normal tissues and establish a rational method of procedure to the end that vision may be restored

DISCUSSION-R P HIGGINS, MD, CORTLAND, N. Y.

Dr R P Higgins There are two classes of cases of Retrobulbar Neuritis, the acute incre or less fulminating form and the slower developing

chronic idiopathic form

The acute form is rapidly developing and may involve one or both eyes. Loss of vision often comes so rapidly that there is not the opportunity to make field examinations to show the presence of scotoma, but the cardinal symptoms are present of sudden loss of vision in one or both eyes, sluggish or no pupillary reaction and an ophthalmoscopic picture of a practically normal fundus with possibly a slight pallor of the temporal half of the disc. There is generally pain on motion and pain on pressure of the eyeball and an etiological factor can be readily demonstrated

The following case is a good example of this type Mrs B, aged 40, who had always previously been well had an attack of grippe with acute The case was treated medi sinus infection cally and the chest symptoms cleared up in about ten days, but the pains in the head did not subside One day she complained that everything looked as though smoke was in the air and objects looked blurred and foggy next day she had no visual perception even of light in either eye The pupils were moderately dilated, were irresponsive to light and with the oplithalmoscope there was practically normal appearances of the fundus X-ray of the sinuses showed some cloudiness of the

The usual operative procedure of splienoids resection of the middle turbinate, opening the posterior cthmoidal cells, and drainage of the sphenoids was done and before the patient left the operating table she could dimly distinguish faces and objects, and by the next day she could see practically as well as ever mention the operative procedures and prompt recovery in this case to show how little organic destruction of the nerve can cause complete blindness In this case there was evidently no destruction of nerve tissue, but probably a pinching of the optic nerve in its passage through the optic foramen or some inflammatory pressure on the nerve in its course backward in the orbit

We were very fortunate in having under our eare at the same time as the above mentioned case, a case of fracture of the skull at the base of the brain and involving the optic This was a boy, aged 17, who was injured in a coasting accident. In this case he had at the time of the accident nearly complete loss of vision with field of vision reduced to a small segment, but the ophthalmoscopic picture showed a swelling of the nerve head with a blurring of the outlines at the edge of the disc with small hemorrhages around the dise and later partial pallor of the disc characteristic of descending atrophy of the nerve Many of the books in describing the ophthalmoscopic picture of the retrobulbar neuritis

speak of the swelling of the nerve head and the small hemorrhages which, in our limited experience, is caused either by traumatism or pressure symptoms such as would cause true optic neuritis or choked disc rather than the usual picture of retrobulbar neuritis.

The more slowly developing chronic forms of the disease are apt to be associated with organic destruction of the nerve tissue and while they are slower developing they are also slower in recovery and may never regain normal vision. Personally I could never understand why toxic amblyopias are always classified as examples of retrobulbar neuritis as the nerve cell affected by the toxic agent is in the ganglion layer of the retina, but these cases are always grouped in this class of cases. It is in these cases that we can demonstrate the enlarged central scotomata and the sluggish pupillary reactions so well described by Dr. Here, too, we get rather negative ophthalmoscopic findings and partial pallor of the disc, which by the way is pretty hard to demonstrate and is generally associated with atrophy of the affected nerve cells of the portion of the retina involved and more or less permanent loss of vision.

These cases are those caused by the more prolonged action of toxins or by septic absorption from some local focus of infection such as we get with infected teeth or tonsils or nasal sinuses which by proximity do not bring on the acutely developing cases. cases of multiple scleroses also fall into this class. It is a question whether the central scotoma in these cases is due to more extreme susceptibility of the fibers of the papillo macular bundle or a lessened resistance of the nerve cells around the macula from which they arise. It may also be due to a local action of the toxin or infection on the fibers from this region as they course backward in the nerve as there is a part of their course where they occupy a sector shaped area on the lateral aspect of the nerve.

One other class of cases in which neither the patient nor the doctor see anything are the common cases of amblyopia ex anopsia. Many times the squinting eye in infancy and early childhood has become straightened in adult life either by glasses or operation, and a realization of its presence and a few questions as to past history together with the refractive error will make the diagnosis clear.

DISCUSSION-THOMAS H. JOHNSON, M.D., NEW YORK CITY

Dr. Thomas H. Johnson: Although there may be no objective signs in retrobulbar neuritis the diagnosis is usually not difficult. The sudden or rapid reduction of central vision with a central scotoma and a comparatively normal peripheral visual field practically make a diagnosis. To determine the etiology and significance of the retrobulbar neuritis, however, is often a problem.

A careful history is important and a thor-

ough physical examination essential.

The importance of careful history taking is shown in the recent reports in the Journal of the A.M.A. this year by Mahoney, and Lillie and Parker of cases of retrobulbar neuritis due to the absorbing of thallium used as a depilatory in toilet creams.

A few years ago I had a patient who came to me with a large absolute bilateral central scotoma. His habits and general physical condition were good. By occupation he was a painter and because of his skill in matching colors he was kept constantly day after day mixing paints by hand. By exclusion a diagnosis of lead poisoning was made, the patient removed from contact with paint and in about 8 months his vision had returned to normal under eliminative treatment.

It is when retrobulbar neuritis appears as an early symptom of multiple sclerosis that its significance is most likely to be not recognized. This is due to the peculiar character

of multiple sclerosis. The symptoms may be transient or remittent. A patient with multiple sclerosis may have a central or paracentral scotoma which disappears after a few weeks with a return of normal vision with or without a later temporal pallor. Likewise transient diplopias are common in the disease, variableness of the symptoms is explained by the pathology, which consists of plaques of tumefaction, exudate and later sclerosis of the myelin sheaths of the nerves involved while the axones may remain normal, partially or wholly destroyed. It is in this disease that a thorough physical examination is cases of retrobulbar neuritis may lead to an early diagnosis.

A retrobulbar neuritis combined with a nystagmus induced by extreme rotation of the eyes, absent abdominal reflexes and the presence of the Babinski reflex make a diagnosis of multiple sclerosis almost certain.

Sachs and Friedman (Multiple Sclerosis, Hoeber Vol. 2, 1921, p. 49) found temporal pallor present in 22.6% of 141 cases of multiple sclerosis. Often we see in routine examinations of the fundi a definite pallor with some apparent excavation of the discs in eyes that prove to be entirely normal. There is a doubt as to the importance of temporal pallor as a diagnostic sign unless there is visual disturbance.

RETROBULBAR NEURITIS. RHINOLOGICAL FINDINGS* By GORDON D. HOOPLE, M.D., SYRACUSE, N. Y.

HAVE had a keen interest in Retrobulbar Neuritis for a long time. Perhaps this is because I learned, soon after my entrance into the rhinologic field that a cousin by the name of Hoople, nearly thirty years ago, was one of the pioneers in this country in the investigation of the rhinological origin of retrobulbar neuritis. Then I had the privilege of association with Dr. Leon O. White, than whom no one has done more for a solution of this problem, both by his own endeavors and the inspiration he gave to others. My association with Dr. White was during my house officership at the Massachusetts Eye and Ear Infirmary and was coincident with his change from radical to more conservative measures in the treatment of retrobulbar neuritis of rhinologie orgin. Finally, retrobulbar neuritis has intrigued me hecause of the difficulties surrounding the solution of its origin. One cannot very well attempt to produce the condition in the human. If the attempt is made to produce it in animals, one cannot know with certainty, that a retrobulbar neuritis has been created, because in establishing this diagnosis, too much depends upon the subjective responses of the victim.

If these difficulties face us, how can we intelligently discuss such a phase of the subject as the rhinological findings? Lacking definite pathological proof as we do, can we say that some cases of retrobulbar neuritis are due to rhinological causes? If so, can we further classify these causes? If we can it must be based upon clinical evidence. Of this we have an abundance. It has been handed down to us by an imposing array of observers whose deductions are reasonable and whose thinking is sound. There is a value in reviewing their work, for from it we can learn much about this obscure condition. One factor must be taken into consideration. We must be aware of the enthusiast, for prejudice warps his judgment and his conclusions may be unsound.

We are confronted with this difficulty the moment we try to determine the percentage of cases due to rbinological causes. Some reporters would have us believe that the nasal accessory sinuses are responsible for 80% of all cases of retrobulbar neuritis Still others, a litle less enthusiastic, insist that 50% of these patients fall into this class. More careful observers give us a different picture. After assigning most of the cases to multiple sclerosis, syphilis, diabetes, gallbladder disease, rheumatism, gout, Leber's disease and tuberculo-

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932

sis, they leave only a small number as due to multiple foci (such as teeth and tonsils), and the sinuses. Only a few of those who observe many cases state definitely the percentages of these various causes. They are all apparently agreed that multiple sclerosis is the most frequent eause. This may be the reason for their reticence in giving percentages to the other causes, knowing as they do, that a later check up may prove the presence of multiple sclerosis rather than some previously assigned cause. With these difficulties in mind it is probably fair to state that the sinuses, per se, are responsible for less than 20% of the total and may be as low as 4 or 5% in some series. Wilmer puts his rhinogenic cases at 11%, Langerbeck at 3.5% and Walker at 4%, and Scheerer, in a series of 203 cases, at 1.5%. If these and other observers are right, then as rhinologists we must be careful that a thorough examination has been made for the exclusion of other causes before we attempt nasal treatment for the cure of this condition. If these percentages are even approximately correct, then the internist and the neurologist hold a more important position in the diagnosis and treatment of this condition than the rhinologist, spectacular as his may be. One possible and perhaps important exception to the foregoing statement will be noted later when the relation of multiple sclerosis to retrobulbar neuritis will be mentioned. Here then, is our problem—to eliminate, if possible, any causes other than the sinuses; when this has been done, to treat each case on its merits alone. To do this we must know something of the anatomical and pathological findings in these cases. What are they and how should we make use of them in treating this condi-

There are three anatomical factors which have possible important relations to the subject under discussion. These are, first—the size and shape of the sinuses; second—dehiscences between the sinuses and the optic nerve, and third—the size of the optic foramen. The first two, the size and shape of the sinuses and dehiscences, would make us think of involvement of the optic nerve on the basis of the toxic theory as contrasted to the third, the size of the optic foramen, which could only affect the nerve by pressure.

The nasal accessory sinuses are formed by a pneumatization of the various bones in which they lie and after which they take their names. In some cases there is very litle pneumatization and the size of the sinuses is small. Then the great majority have an average

pneumatization with an average size to the Finally there is a third group in which there is an almost excessive pneumatization and in these cases the sinuses are, comparatively, very large. The capacity of the sphenoid sinues may be as great as 20 or 30 c.c. It is in this latter group that the walls of the sinuses are thin. The possibility of infection passing through these thin walls to the neighboring tissues is certainly greater than in the cases where the sinus walls are of average, or even greater thickness. It is in this group too, because of the excessive pneumatization, that the posterior ethmoidal and sphenoidal sinuses come into closer relation to the optic nerve. In fact, the optic nerve may pass through the sphenoid or one of the posterior ethmoid cells. Various bizarre relations may exist. Oliver and Crowe enumerate some which they found in the London Collection.

1. Left posterior ethmoid cell forms the medial wall of the canalis opticus on the right.

2. Right posterior ethmoid cell forms the lower and medial walls of the canalis opticus on both sides and the wall of the entire sulcus opticus.

3. Left sphenoid sinus forms the lower walls

of the canalis opticus on the right.

4. Left sphenoid sinus forms the lower and medial walls of the canalis opticus on both sides and the wall of the entire sulcus opticus.

An operator must be aware that these anatomical irregularities can exist and be pre-

pared to deal with them.

Only a word need be said about dehiscences. It is evident that infection can travel easily from the sinuses to surrounding parts if there are openings in the sinus walls. Walker calls attention, amongst others, to the following dehiscences: one-between the sphenoidal sinus and the optic chiasm and hypophysis; twothe bony wall of the canalis opticus has a thickness of from 0.2 to 2 mm. and is usually 2 to 5 mm. from the ostium of the sphenoid but with the canal in the sinus, dehiscences may vary from pin-point size to a complete surrounding of the nerve so that it may lie free in the sinus; three—this also may be true of a posterior ethmoidal cell. Walker points out that so far as he knows, retrobulbar neuritis cases at autopsy do not show a great percentage of dehiscences, but the search for these calls for expert dissection and are devastating and this may account for the fact that they have not been revealed.

Finally, in the anatomical discussion we come to the finding which was so well studied by Dr. Leon White, i.e., the size of the optic foramen. In 164 skulls the average size of this foramen was 5.19 mm. Those which were 5.5 mm. or 6 mm. in diameter, were found-

always to be round. Several which were 5 mm. in diameter were slightly oval. Those which were around 4.5 mm. were flattened at the top and were all partly surrounded by pneumatized cells. In these latter cases there was a frequency of dehiscences. Thus, the three important anatomical factors are often combined in the same case—excessive pneumatization of the sinuses with unusual shape and size, the presence of dehiscences and a small optic canal. It is reasonable to assume if infection is present in such a case, there is more likelihood of optic nerve involvement than in cases where those factors are not present. There are then, anatomical findings which seem important in the consideration of the etiology of retrobulbar neuritis.

When we come to discussion of the pathological aspect of the relation between sinus infection and retrobulbar neuritis, we are faced with difficulties. There is an abundance of evidence that in some cases of retrobulbar neuritis, a sinusitis is also present. There is even further but less abundant evidence that in some cases the infection has passed beyond the confines of the sinuses to surrounding tissues. In all these instances it can only be assumed that the sinus infection caused the retrobulbar neuritis. Here is our chief difficulty, in the attempt to prove whether or not sinusitis causes retrobulbar neuritis. We cannot establish the condition in animals for we cannot very well measure a loss in their central vision. The pathological proof, I feel, will be found when we have studied a sufficient number of optic nerves of patients suffering from this condition. It will take a long time to collect a sufficient number, for retrobulbar neuritis does not cause death and these nerves, to give the most information, will have to be studied shortly after the onset of symptoms. A few observers have started us on the trail. Redslob reported a case of a child with bronchopneumonia, who had a purulent sphenoiditis. At autopsy the diplococci were found in the optic nerve. Pickworth reported that a perforation through the sella allowed invasion of the optic nerve with demonstrable cocci in its sheath. In this case neither the sphenoiditis nor optic neuritis were evident in life. TenDoesschote's case had a chronic pansinusitis with a death from pneumonia. Diplococci were found in the sinus mucosa, in the bone marrow between the sphenoid and the optic nerve and in the dural sheath of the optic nerve and in its septa. VanderHoeve demonstrated pathologically in one case how inflammation can spread from the sinus to the optic nerve by penetrating the bony separating wall. In this case there was degeneration of the papillo macular bundle. In none of these cases

was there any ante mortem report of loss of central vision, yet they all show the possibility of involvement of the optic nerve when sinusitis is present. Two cases were reported where a central scotoma had been present for several months. In neither of these was there any significant pathological changes in the optic nerve at autopsy. One of these was reported by VanderHoeve; the other by Birsh Herschfeld. In their reports mention was made that the vein and capillaries of the nerve and sheath were more filled than usual. Pilcher attempted to show in rabbits that infection could travel to the optic nerve. He injected dyes into the sinuses and produced a sinusitis but none entered the nerve sheaths. Finally Behr conducted a very interesting experiment in which he transferred portions of the ethmoid bone from patients afflicted with multiple sclerosis to rabbits and produced paresis and symptoms of paralysis as well as changes in the optic nerve which closely resembled the changes in retrobulbar neuritis.

For an understanding of the possible pathological route by which a sinusitis may spread to the optic nerve, we can turn to an article by Herzog. He pointed out that when there were extensive marrow spaces in the bone between the optic canal and the sphenoid, they were intimately connected with the submucosa of the sinus and the dura or sheath of the optic nerve by means of cellular processes running from the dura into these spaces where they blended with cellular elements derived from the submucosa of the sphenoid sinus extending into the same spaces. There were many more openings into the marrow spaces from the sinus side rather than the optie nerve side. He demonstrated infection in the marrow spaces from the sphenoid side and found edema and other inflammatory changes in the marrow spaces without any changes in the sinus mucosa. Slight inflammatory changes in the superficial layer of the sinus mucosa could disappear while infection continued in the marrow spaces. He used this as an explanation of negative sinus findings in operation on retrobulbar neuritis cases.

Numerous observers have reported similar findings. These include White, Wright, Oliver and Crowe, O. Beck and J. Beck, and others. In their cases they report edema, fibrous hyperplasia and chronic inflammatory changes in the mucosa, sometimes involving the bone with a non-inflammatory rarefaction. All of them report these findings in retrobulbar neuritis cases where no pus could be demonstrated in the sinuses at operation. There is abundant evidence then, that despite apparently negative operative findings, infection of the sinus mucosa and bony walls can be present.

I have purposely refrained from a discussion of the merits of the pressure or toxic theories, and that the papillo-macular bundle of the optic nerve is chiefly involved, believing all this lies within the province of the ophthalmologist. I have tried to report only pathological facts from which certain inferences can be made.

Before considering the clinical aspects of the subject, one item should be brought under discussion. That is the relation between sinusitis, retrobulbar neuritis and multiple sclerosis. Numerous reporters, amongst whom are Symonds, Zeagler, Scheerer, Davis, Langerbeck and Fleischer, mention that retrobulbar neuritis may precede or be the first symptom of multiple sclerosis. Fleischer reports a followup of thirty cases of retrobulbar neuritis in which sixty-six per cent developed what he diagnosed multiple sclerosis. This question naturally arises; if retrobulbar neuritis may be caused by sinusitis, and many cases of retrobulbar neuritis apparently develop into a multiple sclerosis, may it not be possible that the virus which is the cause of multiple sclerosis has its entrance into the central nervous system by way of the sinuses and the optic nerve? In the light of our present knowledge the question cannot be answered positively in the affirmative. W. H. Wilmer has raised this question. He mentions that the papillo-macular bundle is a prolongation of the white matter of the brain, having medullated fibres, no sheaths or cells of Schwann, but containing true glial cells. Reaction to disease here would be as in the central nervous system. He feels that multiple sclerosis is due to a filterable virus and that it is quite possible for the portal of entry to be in the sinuses. Later, H. H. Vail mentioned the same findings and possible conclusions and asks, "Shall we deprive patients the possible chance of avoiding or postponing the onset of multiple sclerosis by neglecting to drain surgically those nasal sinuses nearest the optic nerve? I mentioned above that the internist and neurologist hold a more important position in the diagnosis and treatment of retrobulbar neuritis than the rhinologist, if the rhinologist is responsible for those cases only, in which all causes other than rhinological have been excluded. However, if we should consider all these cases in the light of possible invasion of the central nervous system with a filterable virus, then the position of the rhinologist would be an extremely important one and a tremendously important responsibility would rest on his shoulders. Here is a field for further investigation, where the work of Behr in producing what appears to be multiple sclerosis in rabbits should be substantiated and augmented. There

are possibilities, the importance of which cannot be denied. Yet, if proven, they will not lessen the responsibility nor the problems of the rhinologist, though he might be less hesitant to recommend operative procedures if he knew with some certainty the probable ultimate outcome of a particular case. This brings us then, to a discussion of some of the clinical aspects of this problem.

After a diagnosis of retrobulbar neuritis has been made by an ophthalmologist, it would seem that the next step in such a case would be consultation with a competent internist. He should determine the presence or absence of various possible causes or foci of infection. Even if he cannot isolate such, his value in the case cannot be denied, for proper care of diet, hygiene, etc., are of unquestionable worth in these cases. The next step should be consultation with those specialists who can help in discovering other foci. It is here that the rhinologist has his part. I think there can be no question about the advisability of operative procedures in the event that a purulent sinusitis is present. The ultra conservatives may say that no proof has yet been established that sinusitis causes retrobulbar neuritis, (and I think that is so), but any clinician would recommend operative measures if he had unearthed a purulent sinusitis in a patient who was going blind. There can be equal certainty that there should not be wholesale surgery. If the observations of the men mentioned above are correct, purulent sinusitis is present in only a small percentage of the cases.

change in attitude toward surgery of the sinuses of the posterior series by Dr. Leon White, cannot be passed by lightly. One who did so much in the investigation of this condition and who knew so much about it, must have had some real reason for saying that he felt 85% of the cases would recover on conservative local treatment and that teeth and tonsils were responsible for more cases than the sphenoid and posterior ethmoid.

What, then, should we do in a case where no discernible foci, or other causes are present and yet the patient's eyesight is seriously affected and with the passing of time after the use of local treatment there is no improvement in vision? It is my feeling that there can be no set rule. Each case must be judged on its own merits. The presence of large sinuses with a small optic foramen should be taken into consideration. We know that many rhinologists have had cases which did not have any operative procedures for one reason or another, where the vision gradually failed with subsequent development of optic atrophy. On the other hand, there are many cases on record where operation on the sinuses in face of negative findings has restored the vision to normal, by what means we cannot say. I feel that these facts should be brought to the attention of such a patient and let him decide whether or not he wishes to gamble on the success of operative procedures. I must confess that if the decision were mine to make, I should ask a competent rhinologist to do the operation.

DISCUSSION-WM. P. HALL, M.D., UTICA, N. Y.

It is a pleasure indeed to listen to such a complete coverage as given by Dr. Hoople, concerning the present opinion relative to nose pathology as one source of retrobulbar neuritis and especially to have it presented in such a conservative way.

When we consider that the men would vary from 1.5% to 80% in weighing the nose relationship, this discrepancy is rather startling and enlightening.

To me it shows while sinus involvement must have a place in the etiology, at the same time we must keep in mind the other toxic sources. In my own experience 5% relationship would about cover. It has been my opinion that the infection travels from the sinuses through the lymphatics to the optic nerve. One difficulty with which to contend is when a combined causation is present and this is particularly true in chronic cases.

I have in mind a recent acute case of a girl fifteen years old of the neurotic type, pain through the affected eye, hardly controllable

by narcotics or any anodyne. This case presented a marked papillitis and later bordering on a choked disc. With nausea and projectile vomiting there was good reason to suspect a Nose examination showed a brain tumor. marked hypertrophy of the middle turbinal but no pus above or below. There was a moderate mucus drainage. This case had no temperature, radiograph of sinuses indicated a normal state as well as the sella turcica area. was 20/100 and had been diminishing for several days. However, I removed the anterior two-thirds of the middle turbinal for better ventilation and drainage and within a few days vision was 20/40 but pain and papillitis persisted. Suspecting an endocrine imbalance she was put on the mixed glands and in a few days pain disappeared, vision was 20/15 and has continued well.

My experience has indicated that the very purulent posterior ethmoiditis and sphenoiditis are not as apt to lead to optic nerve trouble as the cases of obstructive nature, involving particularly the middle turbinal or a high deviation of the septum

I like to concede that we must not overlook sinusitis as a positive source of retrobulbar neuritis and at the same time emphasizing the need to keep in mind possible associative and combined factors which are listed mainly under the head of the toxemias

DISCUSSION-FRANK H VALONE, MD UTICA, N Y

I wish to congratulate Dr Hoople on the splendid paper lie has presented

He has not only gone into the clinical aspects but also into the anatomical and patho

logical findings What part is played by disease of the para nasal sinuses in the production of retrobulbar neuritis is still the cause of great discussions Only recently I had the pleasure of listening to a talk given by Dr Mullins of Cleveland on this subject, in which he emphatically stated that he had never seen a case of retrobulbar neuritis due to sinus disease

So that it seems to me that we are still con-

fronted with these questions

1 Can sinus disease produce retrobulbar

neuritis?

2 Can retrobulbar neuritis be due to discased sinuses of which there is no clinical or

Roentgenologic evidence? If we accept the pathological findings of such observers as Vander Hoeve, Pickworth and Redslob we must admit that sinus infec tion can produce retrobulbar neuritis, while the work of Herzog confirmed by similar findings of such men as White, Wright, Oliver,

Crowe and the two Becks seems to substantiate the contention that retrobulbar neuritis can be produced by sinusitis of which there is no elinical or Roentgenologic evidence

Sinusitis according to the most conservative, is responsible for 35% of all eases of retro bulbar neuritis, multiple sclerosis for more than 50%, while syphilis gout, rheumatism brain tumors, pituitary disease, and the teeth and tonsils are other important causes of retro bulbar neuritis Yet, according to Gifford of Chicago, there still remain 15-20% of the cases of retrobulbar neuritis in which in spite of the most diligent search, no etiological factor can be found

These are the cases in which we are confronted with the question. Shall we operate on the sphenoid and ethinoids, or shall we not operate?

The answer I believe, is one of personal opinion but were my vision seriously affected from a retrobulbar neuritis, and if I faced the possibility of permanent loss of vision due to a subsequent optic atrophy, I feel as the writer does, that I would call on a competent rhinol ogist to operate on my sinuses

RETROBULBAR NEURITIS*

By ALBERT C. SNELL, M.D., ROCHESTER, N. Y.

TRUE retrobulbar neuritis implies that there is an inflammation of the optic nerve stem posterior to the globe. Generally such an inflammation is confined to the orbital portion. The inflammation may involve (1) either the papillo-macular bundleaxial neuritis, (2) the peripheral fibers onlyperipheral neuritis, or (3) the entire nervediffuse neuritis. The latter may involve isolated patches or the entire nerve may be in-The visual fields will reveal which portion of the nerve is involved in the inflammatory process. In all three types of retrobulbar neuritis there may or there may not be ophthalmoscopic findings. In the terminal stage in all three types there may be found secondary optic atrophy or complete recovery without clinical lesions and with full restoration of vision. The course may be acute or chronic.

A differential diagnosis between optic neuritis and retrobulbar neuritis is impossible on an anatomical basis. The usual differentiation depends on symptoms and signs or their absence. The inflammation commonly classified as optic neuritis evidently is always retrobulbar but it is not so designated. It is impossible to conceive of an optic neuritis which does not involve some portion of the optic nerve which lies posterior to the globe. those cases which do have ophthalmoscopic findings although evidently the inflammation is retrobulbar, are classified as optic neuritis, and, by general custom, only those cases in which there is no papillitis, no papilloedema, and no other ophthalmoscopic findings, are diagnosed as retrobulbar neuritis: That is, a diagnosis of retrobulbar neuritis is made when there is loss of vision without fundus signs of neuritis, with the exception that some definite optic nerve diseases are not included in this definition; e.g., tobacco amblyopia and central nervous diseases.

Hence the diagnosis of retrobulbar neuritis is largely a matter of definition or of personal opinion. For this reason there is much confusion concerning the cause, frequency and nature of the disease classed under this term. By some authors toxic amblyopias, especially alcohol and tobacco, are regarded as definite clinical entities and are not classed as retrobulbar, by others they are so classed. Fuchs thinks that a descending optic neuritis should be distinguished from a retrobulbar neuritis, though by most authors—multiple sclerosis is regarded as one of the most frequent causes of

retrobulbar neuritis. Thus those, who include as retrobulbar all cases in which the orbital part of the optic nerve is involved in the inflammation, find retrobulbar neuritis of frequent occurrence; while those who exclude all toxic amblyopias, descending neuritis, central nervous disease, as well as those cases which have ophthalmoscopic signs of optic neuritis, find relatively few cases of retrobulbar neuritis.

The only constant symptom of retrobulbar neuritis is loss of vision which may be complete or partial. This may be central, peripheral, or both, with the accompanying characteristic field changes. In the axial type there is central scotoma, relative or absolute-at times absolute only for colors, especially for red and green. See Figs. 1, 2, 3, 4 and 5. The absolute central scotomas are usually found in the acute cases, and even when there is complete sudden blindness the periphery of the field clears first leaving a central scotoma which later may disappear or leave some permanent loss of central acuity. In the peripheral type of retrobulbar neuritis there is usually an enlarged blind spot. This may be associated with decrease of visual acuity but rarely is there an absolute central scotoma. or central visual acuity may not be affected. See Figs. 6, 7 and 8. Peripheral retrobulbar neuritis is generally unilateral, while the acute axial type is bilateral in fifty per cent of all cases. The toxic amblyopias are also usually bilateral.

Since the pathology, etiology, treatment and prognosis of retrobulbar neuritis are still obscure many contributions concerning all these phases may be found in medical literature. It is not the purpose of this paper to review this voluminous literature or to discuss in detail these phases of the subject but to present to you simply a clinical study of some acute cases which have come under our observation. Any one interested in a review of the subject I refer to a recent contribution by Sanford Gifford, Archives of Ophthalmology Vol. 5, p. 276, and to the papers listed therein.

The chronic cases of retrobulbar neuritis are more common than the acute if the toxic amblyopias of tobacco-alcohol are included. In our experience we have recorded 138 cases (including tobacco amblyopia); of these 104 were chronic, 10 acute alcoholic, and 24 acute due to various causes. Only these latter 24 cases will be considered here. Twenty of the acute cases are classified as axial and three as peripheral, one was diffuse.

The following is a summary of these 20 cases

^{*} Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

371

of axial neuritis: ages-9 months to 62 years: onset-sudden in 17 cases (2 to 8 days), 3 gradual (2 weeks to 3 months): recoverycomplete in a week or two in 18 cases, one died, one (age 62 years) unimproved: causeschronic alcoholism 4, lues 2, mixed foci of infection 3, one each of pneumonia, tuberculosis, multiple sclerosis, urethritis (g.c.), diabetes, mastoid, and surgical trauma (sinus). In 6 cases no cause was found. All had central scotoma or were blind. In 9 the affection was bilateral, 5 having severe loss of visual acuity in both eyes, and in 4 the visual acuity in one eye was slightly reduced: All had negative fundi at first, later 2 showed slight ocdema of the discs, one papilloedema, two bilateral neuritis, and one panophthalmitis (iritis, eyclitis, retinitis, etc.). All these cases had normal blind spots except where the scotoma included this. The scotoma varied greatly in size as is shown in illustrations. In approximately 50% of the eyes the scotomas were absolute, the others were relative or only for color. In the blind cases there was a tendency for the peripheral vision to be restored first leaving a central or paracentral scotoma.

Treatment: Most of these cases were hospitalized and complete physical and laboratory examinations were made by the internist, neurologist and other specialists, including an examination of the nose and sinuses. They were put to bed, placed on a moderate diet, and elimination was carefully attended to. Pilocarpine sweats were given in 9 cases and 4 cases had no medication. In 9 the treatment was either specific, directed to foci of infection, or to general conditions. We did not do a routine tuberculin test. In none of these acute cases did we open nor treat the sinuses except in one case. In this a nasal and sinus operation was followed by an acute amaurosis the following day.

Three cases are presented to illustrate the peripheral type of retrobulbar neuritis. All of these cases had infected sinuses. All were unilateral. In all the onset was acute—2 to 4 days. In one visual acuity was restored to normal in 11 days, in one it required three years for restoration of normal acuity, in the third final outcome was unknown. Fields illustrating the enlarged blind spots of these cases are shown. In all sinuses were opened and treated according to the orthodox method.

It would seem that in these three cases there must have been a direct inflammatory extension from the walls of the sinus to the peripheral structures of the optic nerve.

The diffuse type of retrobulbar neuritis is found among the chronic toxic amblyopias, especially those due to tobacco-alcohol, which will not be considered in this communication.

One additional case is presented briefly since it illustrates the difficulty in making a complete and positive diagnosis during the early period of the optic nerve involvement, and the changing characteristics which required a revision of a tentative diagnosis.

Case report: C. Scanlon, 42 years of age: First consultation Sept. 29, 1917: History: for two months past has observed a recurrent disturbance of vision in right eye lasting one or two days, and for past two weeks vision has been misty. General health good—no serious illness.

Ophthalmoscopic examination: Right eye fundus negative; visual acuity 2/200; blind spot is very much enlarged—See Fig. 9: Form field normal for 10 mm white object. Left eye normal fundus and fields; visual acuity 20/25; Wassermann, sinus and physical examination negative. Diagnosis—retrobulbar neuritis,

April 14, 1919: Right eye third degree optic atrophy; no light perception. Left eye v = 10/200; nerve head shows first degree atrophy; field cut concentrically to 30°; Wassermann negative, repeated tests; sinus negative. Diagnosis—descending optic atrophy.

Nov. 7, 1919: X-ray revealed floor of sella

completely absorbed.

Dec., 1919: Dr. Frazier removed a parasellar tumor using the nasal route.

Apr. 16, 1921: O.S.V. = 20/25. Peripheral fields cut, nerve white. O.D. blind—3rd degree optic atrophy.

Aug. 6, 1923: O.S.V. = 10/200, optic

atrophy.

The following is taken from a contribution by Langenbeck (Arch. of Ophthal. p. 226, Vol. 87) who tabulates the result of his study of 176 cases of retrobulbar neuritis, giving the etiologic factors found, the number of cascs for each, and their percentages.

Multiple sclerosis	58 cases	33.0%
Multiple sclerosis suspected	14 cases	8.0%
Idiopathic (hereditary) affection	32 cases	18.0%
Lues	13 cases	7.0%
Affection of post masal sinuses	6 cases	3.5%
Sudden loss of blood	5 cases	3.0%
Pregnancy	3 cases	1.7%
Lactation	3 cases	1.7%
Articular rheumatism	1 case	0 6%
Etiology unknown	36 cases	20.0%

To this list other reported etiologic conditions, found in reports of retrobulbar neuritis, may be added; arteriosclerosis, burns of the skin, acetonuria, diabetes, tuberculosis, colds, pneumonia, foci of infection (teeth, tonsils, genitourinary), gall bladder, thalium poison (a depilatory), brain abscess, frontal lobe tumor, infectious disease, Leber's disease, menstrual disorders, intestinal autointoxica-

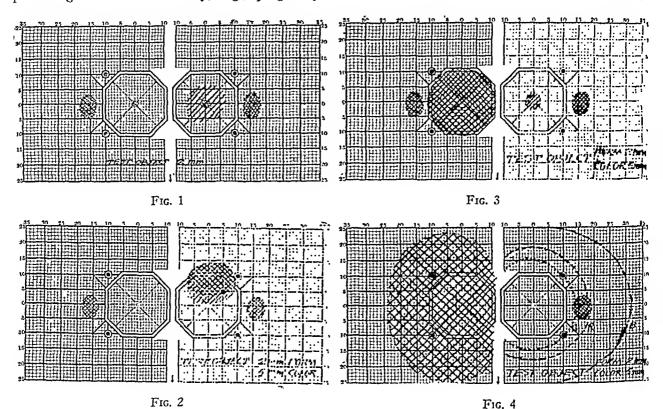

tion, multiple foci of infection, encephalitis,

ependymitis and trauma.

This formidable list of diseases, each of which may be conceded as a possible etiologic factor, differ greatly in their nature but most are capable of producing toxins. Multiple sclerosis is the producing cause in approximately 33% of all cases and some remaining causes may be regarded as contributory by producing a state of debility, e.g., pregnancy,

statement of a well known rhinologist, and since in many cases no other pathological condition can be found, the sinuses naturally, by exclusion, become the object of our desire to do something. There is no glory or professional profit in a record "cause unknown" or in stating the etiology as idiopathic.

Many of the later contributions indicate that these authors now place less importance on the rhinologic etiology than formerly.

Figs. 1 to 4 illustrate the axial type of retrobulbar neuritis. Fig. 1. A relative central scotoma O.S. and small absolute central scotoma O.D. Fig. 2. Absolute paracentral scotoma. Fig. 3. Large central scotoma O.B., small scotoma for color O.D. Fig. 4. Very large monocular absolute scotoma,

lactation, loss of blood. The relationship to toxemia may be regarded as established. It may also be conceded that the optic nerve may become inflamed by extension of inflammatory processes of adjacent structures and further it may become involved in either an ascending or in a descending neuritis. However, the causal relation between posterior sinusitis and retrobulbar neuritis remains a debatable question, especially its relative importance and its frequency. Many American writers have found in the sinus the chief cause, while others have found it relatively unimportant. As Gifford points out this difference of opinion in regard to the frequency of rhinogenic retrobulbar neuritis is due to the fact that recovery following operation on the sinuses has been regarded as proof of the etiologic relationship. Since there is no such thing as a normal sinus, according to the

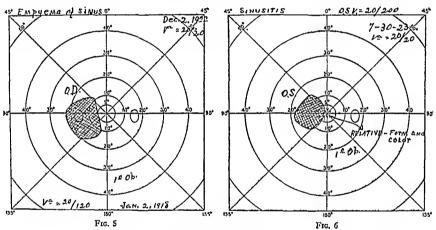

There are some who still hold the view that a simple hyperplastic catarrhal thickening of the membranes of the sinuses is sufficiently pathogenic to cause retrobulbar neuritis. I believe this view to be an extreme one. It is not sustained by my observations. My experience (sinus infection being found in 3% of my cases) is similar to that of Langenbeck who found sinus affections in 3.5% of his cases.

The incidence of any form of ocular involvement is small compared with the common occurrence of sinusitis. Many authors have studied their cases from this point of view but their conclusions vary greatly. However, the possibility of its pathogenesis must be recognized, only one should not hold the sinuses responsible for all of our cases of doubtful etiology.

From our experience with these acute axial

cases there is noted a strong tendency to a spontaneous recovery. The sudden onset and the prompt and complete recovery of many acute cases would seem to indicate that a real inflammation is not always present, but more probably the sudden loss of vision in these is due to stasis, oedema, or more probably to a toxic effect on the more susceptible nerve fibers of the papillomacular bundle. In these tabulated cases although many systemic diseases were found to be present, with the exception of multiple sclerosis, these per se do not seem to be the direct cause for the amaurosis or amblyopia but the toxemias resulting from them do. The progress-a complete recovery within two weeks-and the result of the treatment or its absence would also seem to bear out this conception. Also, since optic will develop multiple sclerosis, and the possibility of frontal lobe or parasellar tumors must not be forgotten.

The proper management and early treatment of acute retrobulbar neuritis is most important whatever may be considered the ctiology, as a prolongation of the inflammatory process may cause irreparable damage to sight in the form of a permanent central scotoma or secondary optic atrophy. Those cases where there is a definite demonstrable sinusitis associated with a blocking of fluid or with empyema require prompt drainage. These acute cases should be hospitalized, regarded as emergencies and all examinations should be undertaken simultaneously so as to avoid delay in instituting the proper treatment after determining the most probable cause. In most of

Figs. 5 and 6 illustrate the peripheral type of retrobulbar neuritis. Fig. 5. A Case of empyemo of sinus. Fig. 6. Acute sinusitis.

nerve fibers do not regenerate, any inflammation of such violence as to produce total blindness or a severe loss of visual acuity cannot reasonably be expected to make a recovery in a week or two and without any later complications. Therefore a toxemia seems to be the more rational explanation in these acute cases which recover so promptly.

Some of these cases demonstrate the propriety of making, at first, a diagnosis of retrobulbar neuritis a tentative one, since with the progress of the disease other symptoms and lesions will often be discovered later which force a change of diagnosis. A number of cases in which no fundus change can be seen at first, later will show macular lesions, others

our cases we gave pilocarpine sweats while the various examinations were being made: Patients were put to bed with attention to elimination but with no other medication. 90% of the acute axial type made a complete recovery or were very much Improved within a week or ten days with this treatment alone. In the acute axial cases I find that the sinuses are very rarely the possible seat of the trouble and therefore can find no ground for advocating post masal surgery in the absence of any definite sinus disease.

I am aware that there are some authorities who still advocate early sinus operations even when the usual rhinologic and roentgenologic examinations are negative. They reason that the

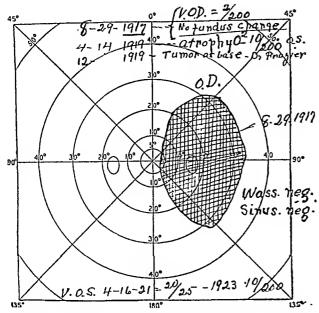

Fig. 7. A field in a case of a parasellar tumor.

proof of the benefit of such operation lies in the fact that many of these patients get well after operation. But the fact, established by the experience of many observers that a large proportion of these cases especially the acute axial type make a spontaneous recovery without surgical interference, shows the fallacy of this post hoc logic.

In all three of our cases of peripheral retrobulbar neuritis there was positive evidence of infected sinuses. Thus it seems to me that in this type one should more strongly place suspicion on the sinuses. However, in any type of retrobulbar neuritis the possibility of sinus disease should be placed beyond mere suspicion before operation. It is my conviction that by far too many sinuses have been the field of unnecessary surgical interference.

The etiology and the pathogenesis of retrobulbar neuritis is not definitely known, therefore all cases should be most carefully studied and when the sinuses are suspected the ophthalmologist and rhinologist should cooperate with scientific methods of investigation both before and after operation if we are to advance our knowledge of this disease and render the proper service to these patients who suffer from the condition.

DISCUSSION-S. B. MARLOW, M.D., SYRACUSE, N. Y.

Dr. Snell has so fully presented the pathology of retrobulbar neuritis that any discussion of his paper can only serve to emphasize some of its contents. The first point is the definition of the condition. As Dr. Snell insists the term retrobulbar neuritis should be restricted to those cases with marked loss of vision in one eye usually without ophthalmoscopic changes, which may be present in rare cases in later stages.

Unfortunately from the point of view of pathological study our knowledge of this disease is based principally upon clinical observation which has resulted in the long list of etiologic conditions cited by Dr. Snell. Disease of the para-nasal sinuses, in recent years advocated as a common factor in these cases, is now declining in favor as a causative agent and the tendency to attribute the disease to disseminated sclerosis seems to be increasing. Whether this latter condition will finally be held to be the cause in a high percentage of cases it is impossible to say. It seems reasonable, however, to warn against making use of this diagnosis without sufficient proof. cases are rare in which it is possible to say with certainty what the etiology is. It may well be that when proof is forthcoming multiple sclerosis will not be found of such etiologic importance as at present and that we shall be forced, for want of a better explanation, to fall back, upon the earlier designation "idiopathic."

Inasmuch as the evidence for a particular etiology has commonly been based upon the results of clinical treatment some excuse for classifying these cases as "idiopathic" is found in a review of (35) cases observed in my father's practice. Prior to 1915 disease of the nose had not appeared in the diagnosis. Taking all the cases together the average period of recovery was 25 days. The average period of recovery in 24 cases which were treated by potassium iodide alone was 22 days. In 5 cases submitted to nasal operation the average period of recovery was 18 days. Three cases with syphilis 57 days, 3 others 31 days. A tentative diagnosis of multiple sclerosis has been made in not more than two or three cases. It is possible that further observation after recovery would have revealed a larger percentage.

In contrast to the treatment described by Dr. Snell in the 20 cases summarised in his paper, not one of the 24 patients in this series treated with potassium iodide and strychemia was hospitalized although a careful inquiry as to possible causes was instituted. It is surprising how rapidly complete restoration of vision occurred in many cases even when the loss was extreme. One case, to be mentioned further, had complete loss of light perception

but vision returned to 6/6 at the end of 21 days. In another vision improved from the counting of fingers to 6/5 in 10 days. A third had only light perception in the beginning but improved to 6/9 after one month. The recovery which took place in these 24 cases is shown in the following table.

TABLE SHOWING VISION AT LAST EXAMINATION

		AFTER RECOVERY HAD									
Cases With	Hand Motion	6/24	6/18	6/12	6/9	6/6	6/5				
Light Perception			_	1	2	1		4			
Hand Motion			1		1			2			
Counting Fingers	1			2	1		1	5			
6/60			1		2	1	_	4			
6/36		1			2		_	3			
6/24				1		1	-	2			
6/18						2		2			
6/12				1		1		2			
	1	1	2	5	8	6	1	24			

Analysis of this table shows that 75 per cent of the cases had vision of 6/36 or worse when first seen, 82½ per cent had vision of 6/12 or better at the last examination. The vision of one case was 6/5, of 6 cases 6/6, of 8 cases 6/9.

From the point of view of etiology and differential diagnosis this small series is of some interest. Syphilis was present in four cases, One early case (1890) was seen by Noyes in New York and diagnosed by him as tobacco amblyopia. In view of the fact that only one

eye was affected that the defect was not limited to the central area but extended over the whole field, complete loss of light perception ensuing, and that recovery took place under potassium iodide and strycliemia to 6/6 in 21 days, this diagnosis was not justified. One case occurred during recovery from cycloplegia. The loss of vision was followed down to hand movements and back to complete recovery This was probably due to periositis at the apex of the orbit. Two cases had scotomata strongly suggestive of disease in the occipital cortex. Two cases were possibly on a pituitary basis One case is strongly suggestive of hys-One case can possibly be explained by a tonsillar infection for after an improvement almost to normal under potassium iodide vision failed following an acute tonsilitis. One recent case was due to thallium poisoning

Some accent experiences in addition to this series have made it particularly apparent that unless a careful ophthalmoscopic examination is conducted through a dilated pupil some cases of central retinitis will be confused with retrobulbar neuritis if the case is seen in its earliest stages before patches of exudate are discerni-These cases of retinitis will present a scotoma sometimes not unlike that of retrobulbar neuritis In this connection the remarks of Mr Richardson Cross in the Discussion on Vascular and other retinal changes in association with general disease in the Transactions of the British Ophthalmological Society for 1913 are of interest. He calls attention to some points of analogy between retrobulbar neuritis and retinitis. He suggests that many cases of retrobulbar neuritis may be due to hidden haemorrhage in the nerve axis, spasm, embol-

ism, or thrombosis of a small vessel to the

nerve fibres.

CLINICAL STUDY OF BCG VACCINATION

By CAMILLE KERESZTURI, M.D., WILLIAM H. PARK, M.D., MILTON LEVINE, M.D., PETER VOGEL, M.D., and MARGARET SACKETT, R.N. NEW YORK CITY DEPARTMENT OF HEALTH

This study was made possible by the kind cooperation of the hospitals and the clinics of New York City. We are especially grateful for clinic facilities for our follow up work to the Children's Services of Bellevic, Fifth Avenue Harlem, Long Island College, Greenpoint Babies' and Sea View Hospitals. For the financial support of our study we are undet ted to the Metropolitin Life Insurance Company and to the Milbank Memorial Fund

THE BCG vaccine is composed of greatly attenuated tubercle bacilli of the bovine type BCG stands for bacilli Calmette Guerin. Calmette chose bovine bacilli because they are less virulent to man than is the human type. In infants the fully virulent bovine bacilli may produce fatal tuberculosis but in older children and in adults, progressive

bovine infection is practically unknown. There appears to be, therefore, no reason to fear that as the child grows, the attenuated bovine type of the bacilli used in the vaccine may become virulent even if they remain alive in the body until adult life. When the cultures are grown under the conditions advocated by Calmette, we do not believe that any culture ever

became virulent. For more than one year before beginning the vaccination of babies we tested with King, the stability of the attenuation of the culture and found that it was constant. We used monkeys as well as many other animals in this investigation. We also tenuated bacilli per milligram. The new-born infants were fed within the first ten days of life with three 10 mgm doses of BCG vaccine. The interval between doses was two days. Recently we have doubled the dose because only half of the infants receiving the original dose

tested the amount of increased resistance to tuberculous infection developed in the animals. Those given the vaccine subcutaneously developed a very considerable resistance while those given it orally developed resistance to a less extent. Convinced that the BCG vaccine

developed a positive tuberculin reaction. But even with this large dose there has not been a great increase in the number of positive reactions evolving. It is the general opinion that a hypersensitiveness to tuberculin evolves along with the development of resistance. Be-

Table 2: Demonstrates the inequality of the type of exposure in the vaccinated and control groups. It gives the number and percentage of the deaths in the different groups.

In Table 2 exposure is considered in all cases from birth on. If, however, we considered the exposure not from birth on but from the date of vaccination or the date of the first tuberculin test, the amount of exposure of the BCG and control cases would have been almost alike.

was safe and developed a considerable resistance in the animals injected with it, we began in 1927 to treat human infants. During the first two years we followed Calmette's advice and administered the vaccine only by the oral method. This vaccine, contains 40,000,000 at-

cause of the frequent lack of the occurrence of a positive tuberculin test in the oral cases and also because of our better results with animals which received the BCG vaccine by injection, we changed our method of administering the BCG vaccine, using instead of the oral or

** Positive or negative Mantoux refers to the first tuberculin test. No ease is admitted in the positive Mantoux control group who shows any sign of clinical tuberculosis other than a positive tuberculin test or maybe some enlarged bilus shadow by x-ray. The positive and negative Mantoux controls are not known since birth.

enteral, the parenteral method. The advantages we gained by this change were -

I Infants vaccinated by either the subcutaneous or intracutaneous method develop a positive tuberculin test in about 84% of the cases which is almost twice as much as the percentage following the oral method we know approximately the number of bacilli mtroduced into the body, while when we give it orally, we have little idea of the amount absorbed from the intestines. We found that the great majority of the bacilli are exerted with the feces.

Acmarks Two control deaths are included, however, these children would not be one year of age if alive

Table 3 Deals with the yearly mortality rate of those oral BCG and Control children whom we knew from the time of their birth and who were exposed sometime during their life to some open tubercular member of their families. The mortality rates are given with and without scoring the cases. There is a decrease in the the mortality among the vaccinated babies in practically every group but there is no decrease in the non tibercular death rate.

As the the deaths both in the control and in the vaccinated group occur within the first year the second and the third years are omitted from this table

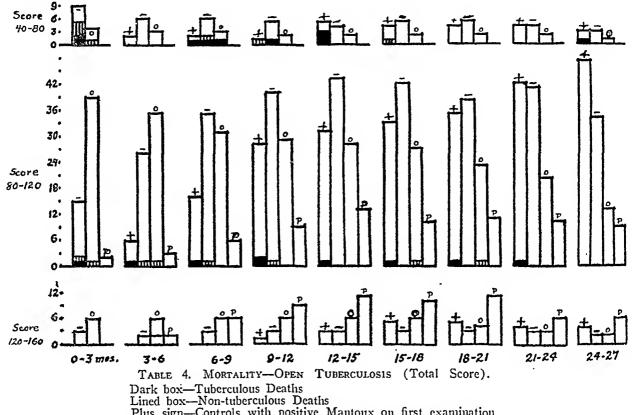

2 The parenteral method is suitable to use on patients of any age if the tuberculin test just preceding the time of vaccination is negative, whereas the oral method is used only on new borns

3 When we inject the vaccine parenterally,

and Park and others show that the parenteral method gives a higher resistance to tubercul losis than does the oral administration of the BCG vaccine. Our study on human beings seems to bear out this point, because among our 272 orally BCG vaccinted babies 2 died

of tuberculosis, whereas, among the 125 parenteral cases, we have no tubercular deaths. However, we must not forget that the parenterally vaccinated babies received their Calmette inoculations at different ages from birtli to 3 years whereas the orally vaccinated in-

above 3 years of age is so slight under any condition that we hardly could evaluate the effect of the vaccine on older subjects. We try to select BCG vaccinated and control children who are alike. However, even if at the start of our follow-up the cases are alike, later on

Plus sign—Controls with positive Mantoux on first examination Minus sign-Controls with negative Mantoux on first examination

Letter O—Orally BCG vaccinated cases Letter P—Parentally BCG Vaccinated cases

Remarks: As all our the deaths occurred in the first 27 months of life of our children, we omitted the part of the table which represents the age groups beyond 27 months.

Table 4: Shows the death rate of children exposed to open tuberculosis per three months periods. The introduction of these three month periods was necessary because the children come under our observation at different ages. This chart illustrates the value of our scoring system by showing that the deaths occur in the two lowest score groups whereas the children in the highly scored group who suffered no handicaps show no mortality. Scoring was done per total life and not by years.

fants were fed with BCG within ten days after birth, and, therefore, being younger were in more danger of developing fatal tuberculosis than was the older parenteral group.

Our plan is to vaccinate only children of the families and observe parallel with these immunized children, a similar group without vaccination, as controls. We employ the oral method of vaccination only in the new-born; the parenteral method, we at first employed on children less than three years of age, but more recently we have accepted for parenteral vaccination, only children under one year of age. We do not wish to extend our study to older children because the tbc mortality and incidence of clinical tuberculosis in children they become dissimilar because of change in the separation conditions and because of unforseen environmental factors in the household, all of which determine the survival chance of the baby and most of which are beyond our control. Therefore, it seemed to us the wisest to take the children as they are, make them controls or vaccinated babies on the basis of a rough analysis when we get them and evaluate their likeness or dissimilarity at the end of each year of their life, thus comparing only similar controls and vacci-In order to nated babies with each other. tacilitate this comparison we had to design a scoring system which according to our present knowledge, covers all the more important

factors which can have an influence on the development of tuberculosis or the escape from it. The constitutional and social factors make up our so called "Social Score". The minimum figure for this factor for the absolutely handicapped children is 0 and for the children who have all the advantage which constitution and social conditions c in give, is 100. Of course, every child has a social score some where between these two extremes. The "TBC Score" handles the tbc influencing factors in the same fashion. The "Total Score" is the sim of the Social and TBC Score's

The items considered in our scoring system with the point values are attributed to them as follows -

TOTAL OF SOCIAL SCORE	0-	100
12 -All other diseases which lessen resistance	0	10
11 —Pertussis with consideration for age Man- toux test and severity	0-	10

There are many little technical details as to the intelligent application of this scoring system which will be discussed in a separate paper to be published. We realize that the points allowed for the individual factors are chosen arbitrarily on the basis of our common sense and experience. However, if we apply the same scoring system to both the vaccinated and control children, the possible error is a rela tive one only and is the same for both groups In this way, even an imperfect scoring system can be of value. As time goes on we shall have the opportunity to improve and modify our scoring. The following series of tables illustrate the necessity of such a scoring system -

TABLE 1 Shows the present status of our BCG study The total number of eases with which we dealt in the past five years, exceeds one thousand

At the meeting of the National TBC Asso eigtion in 1931, we reported 3 the deaths in the oral BCG group. However, on the basis of the histological examination which had not

^{**} The average time of last positive tuberculin test is approximal only because some of the cases were so recently vaccinated that they have no chance yet to lose their positive tuberculin test.

been reported at that time, we have had to classify one of these deaths as due to bronchopneumonia and not to miliary tuberculosis. The details of the case are as follows:-R. M. had been orally vaccinated at birth and was exposed occasionally to a brother who had third stage tuberculosis with positive sputum. Child developed a positive tuberculin test at the age of 5 months, but had no other clinical signs of tuberculosis. She was progressing very nicely until at the age of 31 months, when she developed whooping cough and became feverish, had fine rales over both lung fields and the x-ray, 14 days before death, showed generalized mottling suggestive of miliary tuberculosis. We made the clinical diagnosis of whooping cough complicated by miliary tbc. The child was autopsied at our request, by Medical Examiner, Dr. Fratkin. He reported the case after macroscopical examination as:-

- 1. Bronchopneumonia.
- 2. Peribronchial lymphnode tuberculosis.
- 3. Miliary tuberculosis of the lungs.

Dr. Paul and Miss Mishulow of the Research Laboratories made a bacteriological study of selected material from the organs of the child and found the human type of the bacilli in the lymph gland but no bacilli in the lung tissue. The histological examination of this case failed to show miliary the, but the scattered areas simulating tubercules in the lungs macroscopically and by x-ray proved to be bronchopneumonic foci. The finding of the bacilli can be explained on the basis of a latent quiescent lymphnode tuberculosis, which was suggested by the positive tuberculin test. The cause of death was bronchopneumonia and not the.

The "known from birth controls" are an ideal match for the orally vaccinated BCG babies. The negative Mantoux controls correspond to the parenteral BCG babies as all the children who received BCG vaccine intradermally or subcutaneously had a negative tuberculin test, prior to vaccination. The purpose of following up children who have a positive tuberculin test without other clinical manifestation of tuberculosis is to compare from the point of view of immunity and hypersensitiveness to tuberculin produced by natural infection with the immunity and hypersensitiveness attached to BCG vaccination.

TABLE 5 illustrates the difference between intradermally and subcutaneously vaccinated children both in the primary and secondarily vaccinated groups. Differences in the local lesions, gland enlargements, spleen enlargements, time of first positive Mantoux tests, frequency of positive tuberculin tests and the approximate time of last positive Mantoux tests are tabulated. The routine tuber-

culin test dose in this study was 0.2 mgr. O. T., intradermally.

It is interesting to note in Table 5 that giving the BCG vaccine intradermally we did not observe cold abscesses in the site of the injection as we did in the subcutaneous group. A very much more desirable papulo-macular tuberculide with central necrosis is the typical lesion of the intradermal method.

As far as revaccinations are concerned, our limited experience indicates that local lesion gland enlargement and palpable spleen develops quicker in the revaccinated group than in the primarily immunized children. We are not sure whether the development of the palpable spleen is in causal relationship with the vaccination. As far as tuberculin tests are concerned, we were surprised to see that our revaccinated children much less frequently develop positive tuberculin tests after vaccination and they keep their positive test for a shorter period of time than the children who received only one vaccination. Also the frequency of cold abscesses in the revaccinated subcutaneous group is considerably lower than in the group vaccinated subcutaneously the first time.

As a small experiment in addition to our BCG study, we vaccinated 16 children with heat killed the bacilli. The total number of the cases vaccinated with heat killed the bacilli is so small that we cannot draw any reliable conclusions at present.

Conclusions

- 1. Our five years' study on 413 BCG vaccinated babies indicates that the BCG vaccination is harmless.
- 2. The vaccinated children show a lower tuberculous mortality than similar controls.
- 3. In order to evaluate the effect of the BCG vaccine on the the mortality rate, scoring of the other influencing factors is necessary.
- 4. The handicapped low-score children are best fitted for the evaluation of the BCG vaccine.
- 5. Parenterally vaccinated children became tuberculin positive in 84% of the instances, whereas the orally vaccinated children became so only in 40-50% of the cases.
- 6. Intradermally vaccinated children tolerate higher doses of BCG vaccine and give a more desirable local lesion than the subcutaneously vaccinated ones.
- 7. As a whole, the parenterally BCG vaccinated children show the lowest tbc mortality of all the groups.

DISCUSSION

Kanrad E. Birkhaug, M.D., Rochester, New York: It has appeared of late to many European investigators that conservatism in American medicine was earried a little too far in not giving BCG a trial in this country. It is a hopeful sign, therefore, to have the clinical results of vaccination with BCG in New York City as well as the recent extensive study by Gasparis and Overton at Nashville, Tennessec. A similar study is carried on at Nantreal and surrounding districts. These studies afford a valuable corrective to the attitude assumed by Drs. Petroff, Medlar, Sasano and Watson in this country that BCG is a dangerous virus capable of producing progressive tuberculosis. A six months' visit last year to numerous European centers of BCG vaccination convinced me of the harmlessness of the Calmette-Guerin strain. Likewise, a two-year investigation in my own laboratory on a colony of about 150 guinea-pigs, injected with large doses of whole and dissociated BCG cultures, las yielded results which uphold Calmette's original contention of BCG avirulence and immunizing powers. The series of more than 1,000 cases presented by Dr. Kereszturi suggests that this mode of artificial immunical possible of conducines to be described in the content of the conducines to be described in the content of the conducines of the conducines and the con

nization is capable of producing a higher degree of immunity against tuberculosis than that produced in the controls living under natural conditions. What interests me in particular in this study is the close similarity of cutaneous allergy produced in infants with BCG injeeted enterally and parenterally and the tuberculin sensitivity obtainable in guinea-pigs vaccinated in similar manner. The oral administration of BCG yielded the least allergy and the subcutancous or intradermal in-jection the highest and most durable allergy both in infants and in guinea-pigs. Following the ingestion by mouth of 10 mgm. of BCG in newly-born guinea-pigs I ohtained only 20 to 30% cutaneous allergy and as late as 14 weeks after vaccination, while 100% positive tuberculin reactions were obtained as early as the sixth to eighth week following the parenteral administration of BCG. The reason for this large difference is easily demonstrable by cultural means. Newly-born guineapigs fed 10 mgm. BCG by mouth shed the organisms in the feces in large numbers for four to nine days following the oral administration. BCG viable organisms are only irregularly isolated from mesenteric lymph-glands following the oral feeding. On the other lymph-giands following the oral recoing. On the other hand, BCG injected intradernally remains viable in the local abscess for as long as 110 days, Only recently I was able to isolate viable BCG organisms from 3 very small retroperitoneal glands of a guinea-pig that died from a non-tuberculous intercurrent infection as late as 577 days after the intraperitoneal injection of 20 mgm. of BCG. I believe this is the longest period on record in which a BCG strain has remained viable in animal tissue without producing progressive tuberculosis.

The relationship of cutaneous allergy to the period of survival of BCG vaccinated guinea-pigs, subsequently infected with 250 virulent "H37" tubercle bacilli, is referable to the enteral and parenteral mode of administering the BCG vaccine. The average period of survival of enterally vaccinated animals was 220 days and the controls 197, an almost negligible difference. The average period of survival of subcutaneously vaccinated animals was 300 days, intraperitoneally vaccinated animals was 300 days, intraperitoneally vaccinated animals

mals 304 days and intradermally vaccinated guinea-pigs 420 days. The controls in these series lived only 187 days, less than half the life-span of the intradermally vaccinated animals. There seems very little doubt in this connection that cutaneous allergy is a definite expression of immunity to virulent tuberculous infection.

The occurrence of clinical tuberculosis in probationer unrese with negative tuberculin reactions and exposed to open cases of tuberculosis has been emphasized by Dr. Geer, of St. Paul, Minn., and Drs. Scheel and Heimbeck at Oslo, Norway. The danger of contracting clinical tuberculosis is much less among tuberculin positive probationer nurses entering upon tuberculous wards. The latter authors have clearly demonstrated that a change in cutaneous allergy is readily accomplished by the subcutaneous or intradermal injection of 0.025 mgm. of BCG and that subsequently the resistance of the vaccinated nurses equals that of the tuberculin positive persons. For practical purposes it is very important to bear in mind the figures presented in Dr. Kereszturi's paper that only 10 to 20% of persons vaccinated by mouth become tuberculin positive, while 84% of persons vaccinated either subcutaneously or intradermally become allergic. There seems to be universal agreement that the intradermal mode of vaccination with a dose of 0.025 to 0.05 mgm. BCG is the ideal method which yields the highest percentage of allergy.

Striet isolation of the vaccinated infant from sources of virulent tuberculosis infection until cutaneous allergy has been established is insisted upon by Drs. Wallgren and Wasen at Gothenburgh, Sweden. This earnest endeavor to assess the real immunizing action of BCG is based on the observation that the majority of vaccinated infants become allergic first 4 to 8 weeks after the parenteral BCG vaccination. These authors believe that there is real danger of the infant contracting clinical tuberculosis during this interim if Intimately exposed to open virulent infection. This ideal and logical lygicanic arrangement entails far too many economic and social difficulties to be of practicable significance except in very small experimental series. Tuberculin studies should be insisted upon in every vaccinated infant or adult and revaccination performed until cutaneous allergy is established. Allergy remains the most tangible proof that immunity has been established.

Although it is still too early to assess the real significance of BCG vaccination, there is much evidence available-especially on series of probationer nurses—that BCG does increase resistance to development of clinical tuberculosis in persons intimately exposed to tuberculous infection must of necessity take place in inlants successfully vaccinated with BCG. Little or no fear should be harbored about the potential virulence of the BCG vaccine, if the strain is properly subcultured. My personal experience during the past three years, with a series of strains of BCG obtained from Drs. Calmette, William H. Park and Florence Sabin, has convinced me of the truth in the recent statement by Dr. Stanley A. Griffith, the eminent Cambridge University tuberculosis expert, that the BCG strain may be used as a vaccine without risk of causing progressive tuberculosis.

INHALATION ANESTHESIA*

By JOHN H. EVANS, M.D., BUFFALO, N. Y.

THE safety of an anesthetic agent is dependent chiefly upon three things, namely, its toxicity, its controllability and the qualifications of the one who administers it. A fourth consideration is proper equipment which is essential in its administration of the gaseous anesthetics.

While the factor of controllability belongs alone to the inhalation anesthetics yet there are two of these, namely, chloroform and ethyl chloride, which are such cardiac depressants that not infrequently death results before it is possible to reduce the amount of the anesthetic in the blood stream.

The others in the inhalation group, which include ether, nitrous oxide and ethylene are always under the control of the skillful anesthetist.

When an anesthetic is injected into the blood stream, subcutaneous tissues, spinal canal or rectum, or applied to mucous membranes it is impossible to reduce the amount of the anesthetic agent already absorbed, should an indication arise for doing so. Anesthetics used in this manner are uncontrollable once they have been administered, while the dosage of the inhalation anesthetics is reduced with each exhalation, after the administration of the anesthetic has been discontinued, or it may be reduced more rapidly by the intermitten forcing of oxygen or CO₂ and oxygen into the lungs.

The uncontrollable anesthetics include cocaine, novocaine, neocaine, sodium amytal, pernocton, quinine urea hydrochloride and avertin.

In the writer's opinion the routine use of a controllable anesthetic is justifiable, but the routine use of a toxic uncontrollable anesthetic is questionable.

There are three in the noncontrollable group whose toxicity when used for infiltration anesthesia is so slight that their routine use would seem justifiable. These are novocaine, quinine urea hydrochloride and neocaine. However, when these agents are injected into the spinal fluid it is a more serious procedure in spite of improved technique; it is possible, according to Miller¹ to find reports of one death to 100 cases.

As the death rate for a given anesthetic agent as shown by statistics are not illuminating because the majority of deaths are not reported and the qualifications of the anesthetist are left out of the picture, the selection of an anesthetic is more intelligently arrived at by a study of the anesthetic itself as regards to its effect upon the vital functions of the body. Unless there is a contraindication to the administration of an in-

halation anesthetic the maximum safety in anesthesia is procured when the least toxic of the controllable group is selected and administered by a properly trained anesthetist who has made a study of the case before operation so that he is aware of the patients handicaps.

While the relative merits of the inhalation anesthetics are familiar to you all, it may be

profitable to review them briefly.

ETHER

The chief advantages of ether are its wide margin of safety and its ability to produce muscular relaxation. It is a valuable adjuvant to nitrous-oxide and ethylene.

Its disadvantages are its disagreeable odor, which is objected to by most patients during induction and recovery; its tendency to produce nausea, vomiting and acidosis; it is an irritant to pulmonary tissue and may cause a quiescent tuberculosis to become active and its effect upon diseased kidneys may prove fatal; it is explosive in the presence of a flame or cautery. When skillfully administered it is doubtful whether it is more likely to produce post-operative pneumonia than the other inhalation anesthetics. It is possible that there is more tendency to produce an atelectasis because of mucous plugs, yet this possibility is now guarded against by the administration of CO2 and oxygen, or oxygen under pressure, at the close of the operation.

When the patient is in shock from trauma or other cause, ether should not be used as it is essentially a circulatory depressant in spite of its apparently early stimulating effect and the fall it causes in blood pressures often continues for some time after its administration has been

stopped.

CHLOROFORM

While chloroform has a pleasant odor and is capable of producing muscular relaxation, it is a powerful circulatory depressant. A large percentage of deaths occur during the induction stage. Its prolonged administration may produce degeneration of the liver and kidneys, especially in children, which often results in death. While its use may be justified in obstetrics, the general opinion at the present time is that it should not be used for either major or minor surgery.

NITROUS OXIDE

Nitrous oxide combined with oxygen is the most popular of the inhalation anesthetics from the patients viewpoint. Consciousness is quickly and pleasantly lost and quickly regained. It is not a respiratory irritant and has no deleterious

^{*} Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

effect upon kidney function. It is not a circulatory depressant and there is less tendency to produce nansea, vomiting and acidosis than with ether or chloroform. When skillfully administered the blood pressures are not lowered but

are either maintained or elevated.

The preliminary medication is more important than with the other inhalation anesthetics, especially when muscular relaxation is desired. Relaxation is often inadequate and ether must be added to the gases. While relaxation depends to a certain extent upon the skill and experience of the anesthetist, yet it is impossible to produce sufficient relaxation in every case to meet the demands of the surgeon.

It is important that the anesthetist be thoroughly trained in order to recognize the danger signs, which strange to say, closely resemble

those of too light anesthesia.

It is easy to understand how a novice might have a fatality when he mistakes the signs of danger for those of light anesthesia. His impression would be that death came out of a clear sky without any premonitary symptoms.

When there is too great a reduction of oxygen. muscular spasm occurs. The increasing spastic condition of the muscles of the chest produces prolonged exhalations and the air forced through spastic vocal cords causes phonation which may be a grunt or a piercing cry. The eyes may be wide open due to the spastic condition of the lids and opisthotones may develop. The pupils will dilate and if oxygen is not given the respirations will cease, in which case it may be necessary to force oxygen into the lungs, altho in the great majority of cases the patient will eventually take a deep breath. To be on the safe side the forcing of a breath or two of oxygen is advisable and every gas-oxygen apparatus should be so constructed that this can be quickly accomplished.

As nitrous oxide is not explosive it can safely be given in the presence of a cautery.

It is especially applicable for tonsillectomies, either alone or with the addition of a small percentage of ether as the laryngeal reflexes are not abolished, which is a protection against the inhalation of infected material.

As a smooth anesthesia is difficult to maintain in very young children because of their increased metabolic rate, as compared with older children or adults, the addition of ether is usually advisable. When the metabolic rate is lowered by an appropriate dose of morphine or other narcotic, so that the need for oxygen is reduced, nitrous oxid-oxygen can be satisfactorily administered.

While the indication for a preliminary narcotic is greater in rapidly growing children than in adults, it has been customary to omit it.

The safety of nitrous-oxid-oxygen is more depent upon the skill and experience of the anesthetist than with any other anesthetic.

ETHYLENE

Ethylene; administered with oxygen, has the advantage over nitrous oxide of usually producing a greater degree of nuscular relaxation, while its elimination is somewhat slower. Its effect upon metabolism and vital organs is very similar to that of nitrous oxide. Its disagreeable odor and its explosive properties have prevented its general adoption.

ETHYL CHLORIDE

Ethyl chloride has a rather pleasant odor and for this reason it is used to produce loss of consciousness preliminary to the administration of ether. It is rapidly eliminated by the lungs, there is little tendency to produce nausea and vomiting, the liver and kidneys are little affected and it is not a respiratory irritant. Like chloroform, it markedly depresses the circulation and a momentary overdose may prove fatal.

It is often impossible to secure muscular relaxation without a dangerously large dose.

In the hands of hospital internes it has been found to be too dangerous to be used as a preliminary to ether.

PRELIMINARY MEDICATION

A preliminary narcotic of some kind is usually an advantage as it gives the patient a sense of well being, tends to minimize his fears and makes it possible in most cases to lessen the amount of the inhalation anesthetic.

When nitrous oxide or ethylene is to be the anesthetic preliminary medication is especially desirable not only to aid in securing muscular relaxation but to fortify the patient against post-operative pain as consciousness is so quickly regained.

Over preliminary medication should be avoided in tonsillectomies or other operations where there is liable to be bleeding into the throat. It is important to maintain the laryngeal reflexes to prevent the aspiration of infected material with the possibility of a resultant pneumonia or lung abscess. The writer has omitted all preliminary medication in a series of over 6,000 tonsillectomies in which nitrous-oxid-oxygen was administered without the addition of ether.

The object of not giving morphine or other opiates in these cases was to eliminate the nausea and vomiting which is occasionally produced by these drugs.

In many of these cases the need of preliminary medication was evidenced by the impossibility of maintaining a uniformly smooth anesthesia.

Avertin as a basal anesthetic is still in its trial stage but reports indicate a growing enthusiasm in its favor. The idea of going to sleep in one's own room and not awakening for several hours later is appreciated by most patients.

N. Y. State J. M. March 15, 1933

Its use usually makes it possible to procure muscular relaxation without the addition of ether to nitrous-oxid-oxygen or ethylene-oxygen. A certain per cent of cases require no other anesthetic than the avertin.

It is a valuable addition to the field of anesthesia and surgery. However, it is uncontrollable and occasionally produces circulatory collapse. It may cause necrosis of the intestinal mucous membrane especially when it is not properly prepared for if the temperature is higher than 104 F. hydrobromic acid is split off and dibromacetaldehyde is formed which produces marked irritation. As the laryngeal reflexes are usually abolished it should not be used for operations where blood or vomitus is liable to be present in the throat.

It is important to keep the avertin in the lower bowel so that its absorption is not too rapid.

In view of the fact that avertin is a toxic agent and once given the dose cannot be reduced, its routine use does not seem justifiable.

The deaths which occurred when avertin was employed to produce complete anesthesia led to a lessening of the dose with the idea of obtaining only partial anesthesia so that it would be necessary to use some form of inhalation anesthesia to complete it. When complete anesthesia results from the avertin alone, the dosage is now considered dangerously large.

The writer's experience with avertin is limited to about 50 cases, the first of these being given over two years ago. The reason the number has not been greater is due to his dislike to the marked fall of blood pressures which occurred in some of the cases and to a fatality in which the avertin possibly was a factor. This was a six months old baby to whom a 60 m.g. dose was The proposed craniotomy progressed only to the point of turning back of the skin flap over the cerebellar region when the operation was stopped because of the poor condition of the Nitrous-oxid-oxygen ether was needed to complete the avertin anesthesia. The baby died two hours after leaving the surgery. There was some hemorrhage but apparently not enough to account for the serious condition of the patient. Patients with intracranial pressure are decidedly poor operative risks and it is possible that avertin was not responsible for the fatal outcome.

The writer has been informed of two other deaths following craniotomy in which avertin was used. One died in 12 hours without regaining consciousness while the other regained consciousness but died 36 hours after operation. In the opinion of the anesthetist avertin was not the cause of death.

From the records of 940 cases kindly loaned by the surgeon who operated the cases, the following facts were disclosed:

There were 92, or about 10 per cent in which

no anesthetic other than avertin was required, 13 of which were for laparotomies; of the 13 there were 6 to whom an 80 m.g. dose was given while the other 7 received a 100 m.g. dose. The majority of the other cases were given an 80 m.g. dose, 75 of which were for currettage.

There were 6 cases in which circulatory collapse occurred which was apparently due to avertin. All recovered.

One case developed a post-operative pneumonia due to aspiration of regurgitated stomach contents which contained blood. The patient recovered.

There was one death which was possibly due to avertin. This case was a 36 year old female to whom a 60 m.g. dose was given for currettage and insertion of radium (50 m.g. in a brass capsule), no other anesthetic being required. She died 7 days later from peritonitis which was probably caused by one of two things, either the perforation of the uterus by the currette or by a perforation of the rectum or colon caused by the corroding effect of the avertin. In favor of this later possibility is the fact that the patient had a severe colitis which developed 48 hours after the operation, the colitis progressively growing worse until she died. The urine on the second day showed a heavy trace of albumin and many casts. There was no autopsy.

The following data has been collected from other local sources:

A male of 44 years who suffered from asthma was given an 80 m.g. dose for cholecystectomy, appendectomy and removal of external hemorrhoids; following operation there was marked cyanosis, shallow respirations and imperceptible pulse. Three days later urine showed albumin and casts and there was edema of the thighs and legs. He died on the 14th day.

The surgeon is of the opinion that the avertin was a factor in the cause of death in this case.

A woman of about 50 years developed circulatory shock following an 80 m.g. dose of avertin. The operation was postponed for a few days when it was successfully performed under nitrous-oxid-oxygen anesthesia.

Circulatory collapse and suspension of respirations occurred in a 65 year old male following a prostatectomy—Resucitation measures were successful and he recovered. An 80 m.g. dose of avertin was given in this case.

A 48 year old female was given an 80 m.g. dose of avertin for radical breast amputation. For a week previous to the operation she was given 3 grains of sodium amytal daily, and 9 grains before the injection of the avertin. Ether was used as the supplementary anesthetic. She regained consciousness in 3 hours. After 12 hours she went into a coma which lasted for 6 days. There was contraction of the arms, legs

and one side of the face. The blood chemistry was normal including Wassermann. A spinal puncture was done which was negative—The pressure being only 10 m.m. Following the puncture she regained consciousness and recovered. As there was no pathology discoverable to account for her alarming post-operative condition, the blame apparently falls upon either the sodium amytal or avertin. As it does not seem likely that the doses of sodium amytal given could produce the post-operative condition in this case, the avertin must at least be suspected of doing so.

A female age 27 was given an 80 m.g. dose for a laparotomy. She was unconscious for 12 hours and died in 22 hours. In the opinion of the sur-

geon avertin was the cause of death.

An 80 m.g. dose of avertin given to a 38 year old male for appendectomy was followed by delerium which lasted for five days. The patient recovered. As he was an alcoholic it is probable that avertin was not responsible for the post-

operative delerium.

A female 29 years of age was given an 80 m.g. dose of avertin for an operation upon the lower jaw. Nitrous-oxid-oxygen was employed as the supplementary anesthetic. Following operation her urine which had heen previously negative, showed albumin and casts. She died 42 hours after the operation. There was no autopsy.

Whether or not avertin is helpful in reducing the number of post-operative emboli, as some be-

lieve, is a question.

In going over the records of one of our hospitals for a 12 year period, 1920 to 1932, 49 post-operative emboli were found, or an average of about 4 a year. Of these there were 39 deaths and 13 recoveries. In the year 1931 there were 7 cases of post-operative emboli in 6 of which avertin had been used. Of these there were 5 deaths, and two recoveries.

So far in 1932 there have been three cases of emboli in one of which a 60 m.g. dose of avertin

had been used. This was a male 46 years of age, the operation being for drainage of left antrum and ethmoids. Death occurred ten hours after operation.

The writer has been informed of three other post-operative embolic deaths which occurred in Buffalo following the use of avertin. The deaths in these cases occurred 10, 14 and 21 days respectively, after operation. One of these cases was a male of 62 years who had been treated by his physician for myocarditis. An 80 m.g. of avertin was given for an appendectomy, following which there was a severe colitis which lasted for three weeks, when the patient died suddenly. There was no autopsy.

While it is not probable that avertin was in any way responsible for the production of emboli in these eases, it would not appear that it is instrumental in preventing them, judging from

this limited data.

In the writer's experience in the administration of approximately 35,000 inhalation anesthetics there has been five deaths which occurred

on the operating table.

One patient drowned when her stomach poured out the large amount of fluid with which it was distended; one died of hemorrhage after the lapse of a two-hour operation for toxic goiter, being conscious for ten minutes hefore death; another died of hemorrhage when the necrosed carotid blood vessels gave way following the opening of a peritonsillar abscess; one died during a laminectomy upon the second and third cervical vertebrae which were fractured; and the fifth died when the dura over a large cerebellar tumor was incised and the intracranial pressure suddenly released.

That the anesthetic was directly responsible

for any of these deaths is doubtful.

"AVERTIN" ANESTHESIA

By HERMAN E. PEARSE, JR., M.D., and MARJORY M. WIEDRICH, R.N., ROCHESTER, N. Y.

From the Department of Surgery, the University of Rochester School of Medicine and Dentistry, Rochester, N. Y. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

In the last analysis, the purpose for any anesthetic is to abolish pain, relieve apprehension and facilitate a surgical procedure. There are many drugs which will do this, some better than others. The number of compounds available permits a surgeon to choose the anesthetic that is best suited to the patient's needs. Such a choice

will be based upon the patient's physical condition rather than upon the surgeon's enthusiastic addiction to one particular method. A well rounded anesthetic program must include a variety of drugs. After an experience of two and onehalf years with "Avertin" we feel that it deserves a place on the list of useful anesthetics.

CHEMISTRY AND PHARMACOLOGY

The trade name "Avertin" was used for tribromethyl alcohol prepared in 1923 by Willstatter and Duisberg.¹ The drug was first obtained by the reduction of bromal hydrate in yeast-sugar fermentation, but is now synthesized through the same reduction by alcohol in the presence of aluminum ethoxide. Tribromethyl alcohol (or Tribromethanol) is a white, crystalline substance soluble to a 3.5% solution in water heated to 40° C. (104° F.). Higher temperatures result in the formation of hydrobromic acid and dibromacetaldehyde.

Commercially the substance is marketed in solution with amylene hydrate as "Avertin Fluid." Supposedly each 1 c.c. of "Avertin Fluid" contains 1 gm. of tribromethyl alcohol and 0.5 gm. of amylene hydrate. This combination is important to bear in mind since amylene hydrate (dimethylethylcarbinol) is a potent soporific, being from two to three times as powerful as paraldehyde (Cushny). It is probable that at least a part of the effect of "Avertin Fluid" can be ascribed to the presence of amylene hydrate contained in it. This being true, it is thought best to use the term "Avertin" rather than to speak of Tribromethanol anesthesia.

Absorption. Straub³ has studied the absorption rate after rectal administration of a 3% solution. He found that 50% was absorbed in ten minutes, 86% in twenty-five minutes and the remainder more slowly. As much as 10% remained in the rectum after two hours. There is a rapid rise in the amount of drug in the blood to from six to nine mg. per cent after which the concentration falls, being between 1. and 1.5 mg. per cent when the patient awakens. This rapid absorption gives narcosis quickly. Approximately 75% of the patients are asleep in ten minutes. The faster the solution is injected the sooner will narcosis occur. Rapid injection causes an accentuation of blood pressure fall according to Kennedy.4 At least five minutes should be used for rectal instillation.

Excretion. It was first shown by Endoh⁵ in animals that Tribromethanol was excreted in the urine in conjugation with glycuronic acid. This has been verified in the human by Straub.⁸

Amylene hydrate, the other constituent of "Avertin" is likewise excreted in the urine as a glycuronic acid compound. A portion may be exhaled by the lungs.

This detoxicating process by conjugation with glycuronic acid occurs principally in the liver. The resulting glycuronates are reducing agents and their presence in the urine may lead an observer to confuse them with glucose particularly in diabetics. It is possible to distinguish them since the glycuronates are levorotatory and do not ferment.

THE PHARMACOLOGICAL EFFECT OF "AVERTIN"

Cardiovascular System. Studies on the effect of "Avertin" on the blood chemistry show a rise in blood sugar, a reduction of the glycogen reserve, a fall in blood calcium and no change in pH, N.P.N., urea, uric acid, lactic acid, creatinine or chlorides.^{4, 7, 8} Slight acidosis may occur though this is not a constant finding.⁸

There is apparently no effect on the heart muscle or conducting mechanisms^{9, 10, 11} in ordinary doses. There is likewise no change in the strength of contraction or output per beat.³ However, in larger doses than those used for anesthesia there may be cardiac depression or even systolic arrest.

The circulating blood volume may be diminished.¹² A moderate fall in arterial blood pressure usually occurs which is rarely of significance but may occasionally be alarming.

Respiratory System. The respirations are depressed by "Avertin." This has been demonstrated in experimental animals and in man. Eichholtz felt that the minute volume was unchanged. If respiratory embarrassment occurs the use of carbon-dioxide has been found to be the best stimulant. 14, 15, 16

Excretory System. Kidneys. In the great majority of instances there is no effect upon the kidneys but transient albuminuria has been reported. Experimental studies in nephritic animals¹⁷ show a narrow margin of safety with a close approximation of the anesthetic to the lethal dose as well as increased susceptibility to the drug. "Avertin" is contraindicated in nephritis because of the retardation of its excretion and narrow margin of safety.

Liver. Experimental evidence would indicate that cloudy swelling of the liver occurs¹⁸ with repeated large doses. In the early clinical trials, cases of liver damage occurred. With the relatively small doses used at present this need not be feared ¹⁹ except in the presence of hepatic disease. Biliary disorders without jaundice or hepatitis do not form a contraindication to "Avertin."

CLINICAL USE

Our experience with "Avertin" is derived from 410 cases observed in the past thirty months. During this same time 9,420 anesthetics of all kinds were administered (exclusive of obstetrical cases). Thus, since its introduction in November, 1929, we have used "Avertin" in less than 5% of our cases. At first it was tried for a variety of conditions. As experience was gained it was found to be particularly indicated under certain conditions and the patient's condition permitting, was used as the method of choice. At no time was an effort made to achieve full surgical anesthesia. Instead it was always intended as a basal-anesthetic with the expectation of using supplementary anesthesia.

TECHNIQUE

Pre-operative Preparation. Our routine procedure is to administer a cleansing enema the night before operation and to give hypodermically morphine gr. 1/6 (.010 gm.) and atropine 1/100 gr. (.0006 gm.) one half hour before the "Avertin." This procedure may be modified. enema is not essential. It is better omitted unless given at least six hours before operation. It is not used in hyperthyroid cases since it is desired to keep them in ignorance of their operation. An unaccustomed enema would arouse their susnicion. Likewise in case of emergency the enema is not given. The only effect noted from its omission is a slight delay in absorption. The morphine and atropine are desirable but not necessary. Since morphine is a respiratory depressant the dose of 1/6 gr. (.010 gm.) is not exceeded. If a larger amount has been given either another anesthetic is chosen or the operation is cancelled.

Administration. With each carton of "Avertin" there is inclosed directions for its administration. They need not be repeated here. Suffice to say that a 2.5% solution is made with distilled water heated to 104° F. (40° C.) or less (not lower than 35° C.), tested with Congo red, the exact dose carefully measured and the solution slowly injected into the rectum through a soft rubber catheter. Between five and ten minutes are used for instillation. The blood pressure, pulse, respiration and color are observed.

The patient is left in bed in the ante-room for twenty-five to thirty minutes before being trans-

ferred to the operating table.

Dose. We have adhered to the statement that 0.1 c.c. (100 mg.) per kg. body weight is the maximum safe dose. More has never been given. No more than eight c.c. is ever used for one individual.

The effect of age and general physical condition upon the reaction to the drug should be stressed. Children and excitable adults are resistant, while aged, debilitated, cachectic or toxic

patients are susceptible.
We first used "Avertin" with caution, using. in the majority of patients, 80 mg. per kg. or less. As confidence was gained larger doses were used until 100 mg. per kg. was the usual dose. Now an intermediate dosage is employed as follows:

Hyperthyroid patients and children receive

100 mg. per kg.

Average adult receives 90 mg. per kg. Aged patients, cachectic patients, debilitated patients, very obese patients receive 80 mg.

per kg.

It is interesting to compare the results with this change in dosage. For example, in the initial period 78% of the patients receive 80 mg. per kg. or less, with 96% adequate narcosis. In the next period 77% receive 100 mg. per kg. with 96% nacrosis. At the present time 75% receive 90 mg. per kg. with 93% satisfactory narcosis. It would seem that the changes in dose has had no appreciable effects on the results. This might be expected since no drug given by body weight will have a uniform action. Individual susceptibility determines the result.

In the group studied 28% received 80 mg. per kg. or less, 42% received 90 m. per kg. and 30%

had 100 mg, per kg.

RESULTS

Soon after the rectal instillation of "Avertin" the patient appears drowsy, may yawn or say he "feels sleepy" and then goes quietly to sleep. There is no nausea, struggling, excitement or discomfort. The process is entirely effortless. The majority (about 75%) have their narcotic effect within ten minutes. The pharyngeal reflex is soon abolished after which an airway is inserted. There is no excessive secretion of perspiration or mucous.

The narcotic effect was judged complete (sound asleep) in 68%, incomplete (drowsy with amnesia) in 23%, and absent in 9% of the cases. From the standpoint of basal anesthesia this gives 91% with a satisfactory narcosis. If those with incomplete or absent nareosis are grouped according to dose it is found that 35% received 80 mg., 42% had 90 mg. and 23% had 100 mg. per kg.

The relative use of supplementary anesthetics was as follows:

Nitrous-oxide Oxygen	.59.2%
Ether	18 %
Procaine	6.6%
Procaine	16.2%

Spinal anesthesia is unsafe to use as a supplement for "Avertin" since both depress the blood pressure.

Blood Pressure Changes. The average systolic pressure for the group was 122 mm. Hg. The lowest systolic pressure average 90 mm. Hg. This gives an average fall of 32 mm. Hg., or 26%.

The effect of "Avertin" on the systolic blood pressure was tabulated as follows:

No change or rise	7.5%
Did not fall below 80 mm. Hg	77. %
Lowest systolic pressure between 79-70	8.2%
Lowest systolic pressure between 69-60	4.3%
Lowest systolic pressure between 59-50	2.5%
Lowest systolic pressure between 49-40	0.5%

If 80 mm. Hg. is taken as the "shock" level then in 15.5% of the cases the blood pressure drop was of consequence. It was usually transient and rose spontaneously or with the use of supplementary anesthesia. The operative procedure was never delayed because of this hypotension. In 12% of the cases ephedrine sulphate

was given to sustain the pressure.

The narcosis is of a variable duration. In susceptible individuals it may last for six to eight hours, while in those who are resistant to the effects of the drug anesthesia may last no more than thirty minutes. Nine per cent of the patients did not go to sleep. Some of these were not drowsy, could carry on an intelligent conversation but had complete amnesia.

The usual period of narcosis was from three to five hours. The patients frequently arouse, for a few minutes after returning to their rooms, then go quietly to sleep for several hours. This materially reduces post-operative excitement and promotes a smooth convalescence.

Post-operative Period. When regaining consciousness from "Avertin" the patients appear to be awakening from a normal sleep. The absence of excitement is conspicuous. Nausea or vomiting was recorded in 15.6% of the series.

Respiratory depression with cyanosis was noted in five cases (1.2%). This promptly cleared with the use of oxygen-carbon dioxide inhalation. Post-operative pulmonary complications occurred in sixteen cases (3.9%). This figure corresponds closely with the general incidence of post-operative pulmonary complications (3-4%) as given by Cutler.²⁰

Post-operative excitement occurred in only three cases (0.7%).

One patient had diarrhea for three days. Two patients showed blood in the stools after operation. One of these had blood streaking with the return of the first enema, the other had blood present on three occasions. There was no evidence of colonic ulceration, tenesmus or pain.

In the early use of the drug rectal ulceration occurred. This was due to hydrolysis from standing or excessive heating of the solution. Hydrobromic acid and dibromacetaldehyde were formed, the latter of which is irritating to the intestine. Care to use only freshly prepared and tested solutions should avoid all difficulty on this score.

DEATHS

The work of Karber and Lendle²¹ has shown that full surgical anesthesia is obtained with 65% of the lethal dose. Others¹⁷ have found only 55% of the lethal dose necessary. With the smaller amount used for basal anesthesia this margin of

safety is much greater.

At a German clinical congress in December, 1928,²² it was decided that "Avertin" had a mortality of 1 in 7,500 cases. A more recent analysis is given by Schuberth,²³ who collected 72 so-called "Avertin" deaths from the literature. After careful study he has classified these as follows:

- 18 cases—Insufficient information for critical judgment.
- 23 cases—No reason to consider "Avertin" as cause of death.
- 17 cases—"Avertin" possibly the cause of death.
- 3 cases—"Avertin" probably the cause of death.
- 11 cases—"Avertin" certainly the cause of death.

The first group is separated since there was no information on dose, condition of patient, diagnosis, operation or autopsy findings. If the first two groups are excluded this leaves thirty-one cases in which there is a suspicion or certainty of "Avertin" causing the lethal effect. It was estimated that there were 250,000 cases who had received "Avertin." This gives a mortality of 1 in over 8,000 cases which compares favorably with any anesthetic. The most recent figures on spinal anesthesia give a mortality of 1 in 672 cases.²⁴

In the series here reported (410 cases) there were seven deaths within twenty-four hours of the operation. These cases were reviewed by five surgeons. In six of these cases it was unanimously agreed that "Avertin" was not responsible for death. These six cases were operated upon for (1) large meningioma originating in the olfactory groove; (2) mediastinal tumor; (3) intestinal obstruction; (4) substernal goitre; (5) retroperitoneal tumor; (6) septic hip. Autopsy was performed in four of the cases and confirmed the clinical impression.

In the seventh case it was felt that though "Avertin" was not directly responsible for death yet its influence could not be excluded. This patient, a woman of 69 years, with arteriosclerosis and arteriosclerotic heart disease was operated upon for relief of tracheal compression from a large adenomatous goitre. After giving "Avertin" (90 mg. per kg.) her pulse was 100 per minute and blood pressure 140/80 mm. Hg. Nitrous-oxide oxygen was used as supplementary anesthesia, after which her blood pressure arose to 180/100 mm. Hg. As the right lobe was being resected there was a steady drop in pressure to 65/50 mm. Hg. and she was given ephedrin .050 gm. with improvement in her condition and a rise in blood pressure to 100/80 mm. Hg. The operator felt that the left lobe could safely be removed, but during this procedure the blood pressure dropped to 60/50, the pulse became weak with a rate of 150 and the patient went into extreme shock. The operation was hastily terminated. The operating time was one hour, thirty-five minutes. The estimated blood loss was 250 c.c. The patient was given adrenalin, caffein sodium benzoate, and intravenous glucose. She was placed in shock position and external heat applied, but no benefit was derived. She died two hours after operation without recovering from the shoek. Autopsy

There are several phases to this patient's death that might be considered. In the presence of the arteriosclerotic heart disease would it have been better to use procaine or open ether as the supplementary anesthetie? Could she have had a vascular accident with the rise in systolic pressure to 180 mm. Hg.? This appears improbable. Would she have lived if the operation had been done in two stages? The operator states that he was misled by the apparent improvement after the ephedrine. In retrospect he feels that it would have been better judgment to stop at this time and do the left lobe at a later date. Did the operative manipulation cause the shock and death? The answer to this is doubtful, for on the one hand the patient was an obviously poor risk and on the other hand it must be considered that the surgeon was skillful, the operating time not prolonged and the blood loss moderate.

The reviewers differed in their opinions on this ease. Some thought that "Avertin" might be the chief cause of death. Others thought that it had nothing to do with the outcome. In the absence of post-norten findings it is thought best to consider that "Avertin" could not be excluded as a contributing factor in eausing death, but could not be directly charged with the lethal result.

INDICATIONS

The following arc the operative procedures done under "Avertin":

Thyroidectomy	55 cases
Operations upon the neck	33 cases
Operations upon the mouth, jaw or face	70 00 000
Mastectomy	25 cases
Thoracotomy	14 cases
Miscellaneous operations	42 cases
Herniotomy	

Thyroid operations head the list because of the ease with which the hyperthyroid patient is operated upon under "Avertin." There is no anxious period of waiting for operation. There is no apprehension induced by the sights and sounds of the operating room. There is no psychic shock to cause fluctuations in pulse or blood pressure. The hyperthyroid patient receives tap water enemas for several days prior to operation. "Avertin" is then substituted. The patient goes to sleep in his bed, is shaved and prepared, moved to the operating room, is operated upon and is back in his room for several

hours before he is aware that anything has happened. Thus the principle of Crile to "steal the gland" is realized with a more convenient method.

The absence of excitement, struggle or psychic shock makes "Avertin" desirable in any apprelensive adult or child. The long duration of the anesthesia and the low incidence of struggle or vomiting which would increase intracranial pressure make this anesthetic desirable in brain operations. Dandy²⁵ has commented upon this.

The gastrie operations were listed separately from the laparotomies since the low incidence of nausea and vomiting is desirable in gastrie surgery to prevent hemorrhage or weakening of a suture line. Under laparotomy are listed splenectomy, diaphragmatic herniotomy, appendectomy, colectomy, hysterectomy, release of intestinal obstruction, cholecystectomy, etc. "Avertin" is a satisfactory basal anesthetic for abdominal surgery, but usually requires a supplementary anesthetic for relaxation.

The difficulty in administering inhalation anesthetics for operations about the face, mouth or neek accounts for the number of eases where "Avertin" was used in this region. Here, procaine local anesthesia is the best supplement.

The miscellaneous procedures consisted of operations upon the eye, ear, nose, throat, or extremities, and the use of "Avertin" for sedative in uncontrolled pain, in manie states and in convulsions from tetanus.

The number of times "Avertin" was given for herniotomy or for drainage operations was listed separately merely to show how infrequently it was used for these common procedures. If an abseess is to be opened and drained there is no point in having the patient anesthetized five hours for a five-minute operation.

The principal advantages of "Avertin" have been found to be:

Absence of psychie shock or apprehension.

Amnesia.

Absence of excitement and struggling.

Low incidence of nausea and vomiting with

early ingestion of food and fluids.

Long duration of anesthesia with diminution

in anesthetic burden.

Convenience for operations about the face.

DISADVANTAGES

(1) "Avertin" is contraindicated in severe renal or hepatic disease and in cases with ulcerative lesions of the rectum or colon.

(2) Respiratory depression or obstruction is a relative contraindication since the drug may cause respiratory depression with cyanosis. The addition of the respiratory depression of "Avertin" to a patient who already has embarrassed respirations may eause serious anoxemia.

(3) The long duration of the narcosis may be a disadvantage when only a short, minor opera-

tion is to be done. This long anesthesia is an

asset for major operations.

(4) "Avertin" occasionally,6 though not always,8 causes acidosis. This might be a disadvantage in diabetics. We have noted no deleterious effect in our patients with diabetes.

(5) Any drug administered by a body weight method will have an uncertain action. "Avertin" is no exception to this rule. The variation in individual susceptibility accounts for this effect. Under identical conditions of age, physique and dosage one patient will have surgical anesthesia and another be wide awake.

(6) The patients require constant nursing care until fully conscious. They must be watched for cyanosis or respiratory obstruction from "swallowing the tongue." This need of observation may be a disadvantage with insufficient nursing service.

One the whole, given suitable indications, we feel that "Avertin" has a definite place on any anesthetic program. The amount of its use will depend upon existing conditions, but in a certain percentage of patients it will be indicated as the anesthetic of choice.

SUMMARY

(1) Tribromethanol, originally marketed as "Avertin," is now generally used in solution with amylene hydrate as "Avertin Fluid." Amylene hydrate is a potent soporific being from two to three times as powerful as paraldehyde. Because a part of the narcotic effect is probably caused by this "solvent" it is thought to be more proper to speak of "Avertin" rather than tribromethanol anesthesia.

- (2) The drug has been used in this clinic since November, 1929. During this time 9,420 anesthetics (exclusive of obstetrical analgesia) have been administered, while "Avertin" has been given 410 times. Thus it has been used in less than 5% of our cases.
- (3) In 9% of the cases there was no appreciable effect from the "Avertin." The remaining 91% went quietly to sleep, without excitement or struggle within ten minutes after its rectal instillation. After a period of from three to five hours, the patients regain consciousness without excitement or sweating, with a minimum of nausea or vomiting (15%), and with complete amnesia for events during the anesthetic period.
- (4) It was intended to use "Avertin" for only a basal anesthetic, but 16.2% obtained full surgical anesthesia with the doses used (100 mg. per kg. or less). Of the remainder nitrous oxideoxygen was used in 59.2%, ether in 18% and procaine in 6.6% as a supplementary anesthetic. It was felt that in these cases the amount of anesthetic used and the anesthetic burden on the patient was reduced by the "Avertin."
- (5) In our hands, "Avertin" has been found useful in operations upon hyperthyroid or other apprehensive patients, in gastric and brain surgery, in operations about the mouth or face and in intra-thoracic procedures.

EXPERIMENTAL STUDIES ON SUBARACHNOID ANAESTHESIA

The Effect of Procaine Hydrochloride on the Respiratory Center FRANK WANG COTUL M.D., NEW YORK, N. Y.

From the Laboratory of Surgical Research, University and Bellevue Hospital Medical College, New York City. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

THE possibility of paralysis of the respiratory center by drugs used to induce spinal anaesthesia was recognized by different writers of what may be called the older school of spinal anaesthesia. Among these were Allen, Jonnesco and Babcock. With the advent of the new school, however, under the leadership of Labat, Pitkin, Evans and Koster this danger, far from being emphasized, has been minimized. The introduction of what were thought to be new teclnique and new drugs apparently produced a sense of false security.

Thus Labat1 states, "respiratory failure is not due to the diffusion of the injected fluid to the brain and to the deleterious effects of the drug on the respiratory center." Evans² categorically states, "the respiratory depression is from bulbar anaemia consequent upon the fall of blood pressure." Koster and Kasmans on an experiment in which they failed to cause respiratory paralysis by applying 21/2% neocaine solution to the medulla of a eat, based the conclusion that since neocaine in such a high percentage applied directly was devoid of harmful effects on the respiration, the small amount that diffuses upward from the spinal canal during anacsthesia can certainly cause no harm. This work has apparently been confirmed by Harrison' and Sousa, and has been quoted by a number of writers on the subject as evidence of the impunity with which spinal anaesthesia can be used. It will be shown further along how much justification there is for Knster and Kasman's conclusion.

Bloch, Camus and Hertz, on the other hand, in 1921 demonstrated that stovaine and syncaine when injected into the cisterna magna of the dog caused a sequence of symptoms terminating in paralysis of respiration. Camus' in 1922 showed the same train of events with novocain, and Soupalt's in 1923 could identify the same phenomena in a patient who had received 100 centigrams of novocain in the spinal canal between the first and second lumbar space. CoTui and Standard's recently reported experiments which confirmed Camus.

The experiments were reported in Surgery, Gynccology and Obstetrics, lv, 290, 1932. They will be reviewed below and additional data will be reported.

Dogs were used in these experiments, each dog being anaesthetized with morphine hydrochloride 5 milligrams per kilogram subcutaneously and sodium amytal 25 milligrams per kilogram intravenously.

The costal respiration was registered by a tambour connected with a pneumograph applied around the cliest; while the diaphragmatic respiration was registered by a lever attached to the anterior abdominal wall by a string. A brief explanation of the mechanism of these two systems of recording may be desirable. During inspiration the expansion of the cliest stretches the pneumograph, causing the lever to fall; and the bulging of the abdomen slackens the string attached to it, allowing the lever to fall of its own weight. During inspiration, therefore, both the costal and diaphragmatic levers fall, while during expiration they both rise. The blood pressure was recorded by connecting a registering mercury manometer with the femoral artery,

I. Spinal Injections.-When procaine was introduced into the subarachnoid cavity at the first lumbar space in dosages of 100 to 600 milligrams the following train of phenomena occurred. Both the blood pressure and the pulse pressure registered a fall. There was at first an acceleration of the respiration, both costal and diaphragmatic. At the end of some 3-18 minutes, however, depending upon the dose of the drug given, the bulk of the injected fluid and the rapidity of the injection, there occurred a dissociation of the respiratory mechanism. The costal excursions gradually decreased in amplitude until a complete stoppage occurred, while the diaphragm kept on contracting and even seemed to try to compensate for the intercostal paralysis by increased amplitude. By the use of 2 or even 3 pneumographs at different levels of the chest wall, above the eighth rib, it was demonstrated that this costal paralysis was ascending; that is, the intercostal nerves were paralyzed one after another as the drug diffused upwards. This intercostal paralysis was assumed to be peripheral; that is, the nerve roots were affected where they came in contact with the drug in the subarachnoid space.

Injection into the Cisterna Magna.—When procaine was injected into the cisterna magna, however, an entirely different sequence of events was presented. As small a dose as 60 to 70 milligrams in a 17 to 20 kilogram dog swiftly produced a simultaneous stoppage of both intercostal and diaphragmatic respiration, and a fall in blood pressure without any preliminary rise in response to asphyxia, as would be expected from a normal vasomotor mechanism. Sometimes, however, when the dose injected was small, the blood pressure registered a rise. The effects on the vasomotor mechanism will be taken up later.

The comparatively small size of the dose injected into the cistern and the simultaneous paralysis of the whole respiratory mechanism and the fall in blood pressure, suggest an effect on the medullary centers themselves. The fact that the cisterna magna communicates by the foramina of Luschka and Magendie with the fourth ventricle, on the floor of which are located the respiratory and the vasomotor centers, makes the probability of this direct effect very strong.

Two other possibilities, however, must be con-First, a paralysis of the phrenic and intercostal roots by a diffusion of the drug from the cisterna downward. Offhand, if this were so, we would expect from analogy with our spinal experiments, a paralysis of the diaphragm to occur first, followed by that of the intercostals in a descending order. This, however, was not the case. The second possibility is the permeation of the drug into the cord substance in sufficient quantity to paralyze the neurones arising from the respiratory center and running in the cord down to the anterior horn cells of the phrenic and intercostal The localization experiment described in the next paragraph excludes the last two explanations.

Localization of Action.—By removing the atlas, the second cervical vertebra, and a part of the basilar portion of the occipital bone, the cisterna magna was opened and the inferior aspect of the cerebellum, the closed portion of the medulla, and the upper cervical cord, were exposed. A pledget of cotton soaked in 21/2 per cent solution of procaine in cerebrospinal fluid, carrying about 5 cubic centimeters and containing 150 milligrams of the drug was placed over the closed portion of the medulla and the upper cervical cord. The head of the dog was then tilted slightly upward to allow gravitation of the excess fluid downward. Tracings taken in the course of 30 minutes showed neither respiratory paralysis nor appreciable changes in the blood pressure. This shows that neither downward diffusion nor permeation of the drug into the cord had occurred in sufficient concentration to paralyze either the phrenic and intercostal roots or the neurones going out of the center.

A curved, blunt, capillary pipette was slowly slipped through the posterior medullary vellum into the fourth ventricle, care being taken not to injure the floor of the latter by keeping close to the cerebellum. Tracings taken for about a minute during and after the introduction of the pipette showed that no change due to the mechanical introduction had occurred either in the respiratory or blood pressure curves. Then 2.5 cubic centimeters of the solution containing 75 milligrams of procaine was allowed to flow by gravity through the pipette into the fourth ventricle. In less than 30 seconds the costal breathing stopped, followed soon after by paralysis of

the diaphragm. The blood pressure first showed a rise, then fell to zero, as the dog died.

Our explanation for the occurrence of paralysis when injection was made into the cisterna and for the non-occurrence of paralysis when application was made to the closed portion of the medulla, is that in the first case, in the closed system of an intact cisterna magna, diffusion could take place through the foramina to the fourth ventricle; while in the second case the fluid having been spilled, no vehicle for diffusion was pres-To verify the correctness of this explanation, methylene blue was injected into the cisterna magna of an intact dog in one case and applied to the closed portion of the medulla exposed by an upper cervical laminectomy similar to the one described above in another case. On examination of the brains at the close of the experiment, it was found that in the case of injection into the cisterna magna, the floor of the fourth ventricle was colored blue, whereas in the animal in which the methylene blue was applied to the exposed medulla and upper cervical cord, the floor of the fourth ventricle showed barely any traces of methylene blue.

At this point it may be pertinent to examine the experimental technique by which Koster and Kasman³ and Sousa⁵ obtained results that are so different from the foregoing. Since we duplicated the above experiments on the cat, it cannot be claimed that a difference in the experimental animals accounted for the divergent results. From a description of their experiments and from the accompanying illustrations, it seems evident that instead of applying the drug to the floor of the 4th ventricle they applied it to the closed portion of the medulla. With the cisterna magna opened as demonstrated above, the drug could not diffuse into the 4th ventricle in sufficient concentrations to bring about paralysis of the respiratory center.

In the case of blood pressure, whether a rise or fall is registered depends upon the dose. In some experiments, there was a fall from the beginning of the experiment, in spite of the asphyxia occasioned by the respiratory cessation. This would indicate a primary paralysis of the vasomotor cen-In the experiments with smaller dosage there was either first a rise in blood pressure, followed by a gradual fall to zero in spite of the institution of artificial respiration; or there was a primary rise without any subsequent fall. Whether this rise was due to the asphyxia, or a combination of both factors or to other factors, yet unknown, we are unprepared to say. The fact that paralysis of the respiratory centers occurred first would suggest either that the vasomotor center is not anatomically as exposed to the injected drug or that it is more resistant. The finding of Tatum¹⁰ that in poisoning by cocaine systemically administered, the respiration stops before the heart, is interesting in this connection.

The Difference Between Lethal Doses of Procaine in Normal and in Anaesthetized Animals

As stated before, the above experiments were done on dogs which had been narcotized with morphine and sodium anytal. The dose sufficient to cause respiratory paralysis was found to be 30-70 mg. per dog. (Table II.) In normal, that is, mnarcotized animals, however, it was found that larger doses were required. Tables I and II show the marked differences between the small size of the fatal doses in the case of the narcotized group as compared with the comparatively large sublethal doses in the unnarcotized group.

This difference in the lethal dose between dogs narcotized with sodium amytal and non-narcotized animals, striking even in experiments where no attempt was made at quantitation, brought up the question—What other pharmacologic agents and what disease conditions have this effect of making the respiratory center more vulnerable to the

paralyzing effect of procaine?

The Minimum Lethal Dose of Procaine Intracisternolly. Before proceeding with the investigation of the problem just brought up, it was desirable to determine the minimum lethal dose of procaine eisternally. CoTui11 showed that in dogs, the weight method of determining the minimum lethal dose of novocaine cisternally was not reliable. He found that the spinal length taken from the occipital protuberance to the base of the tail, with the animal in maximum flexion, gave a more reliable index than the weight. Thus, while with the weight as an index, the variations of the lethal dose in an individual dog may range from 30.5 to 72.9 mg.; with the spinal length as an index, the variations lie between 11.4 and 16 mg. Only healthy animals as determined by autopsy were included into the series. Two samples of procaine were used in this and in subsequent in-The M.L.D. of one sample was vestigations. found to be 1.3 to 1.5 mg. per centimeter length, while that of the other sample was 1.4-1.6 per cm.

The Effect of Different Narcotics and Their Combination on the Minimum Lethal Dose of Proceine Introcisternally. Using the two samples of procaine whose minimum lethal dose was de-

*Morphine hydrochloride 5 milligrams per kilogram was given subcutaneously and sodium amytal 25 milligrams per kilogram intravenously before the experiment.

termined above, CoTui¹² determined the lethal doses of procaine intracisternally in dogs that had been narcotized with (1) morphine, (2) morphine scopolamine, (3) morphine-avertin and (4) sodium amytal. Throughout the course of this investigation the two samples used were continually cheeked against normal dogs in order to assure ourselves that neither the procaine used had changed in potency nor the animals used in sensitiveness.

In the case of morphine (Table II), it was found that of 8 dogs receiving subcutaneously 5 or 10 mg. of morphine per kilogram, all survived from 1.33-1.5 mg. of procaine per cm. spinal length, the M.L.D. of the sample being 1.45-1.60 mg. Of 3 dogs receiving 30 mg. morphine hydrochloride per kilogram, all died from 1.38-1.4 mg. procaine per cm. spinal length. Thus it appears that, morphine in small effective doses causes no appreciable reduction in the lethal dose of procaine cisternally, although in large doses a reduction takes place.

In the case of morphine scopolantine, of 6 dogs receiving subcutaneously 5-10 mg. morphine and .67 mg. of scopolamine per kilogram, 5 survived from a dose of 1.45 mg. procaine per cm. and 1 died from 1.5 mg. a dose well within the mininum lethal zone. So that morphine scopolamine narcosis seems to cause no appreciable reduction in the lethal dose of procaine.

Of 4 dogs receiving subcutaneously, 2.5 mg. morphine per kilogram and 100 mg. per kilogram of avertin rectally, 3 survived from 1.4 mg. procaine per cm., while one died. Of 4 dogs receiving twice the amount of morphine but the same amount of avertin, one survived from a dose of 1.4 mg. procaine per cm. spinal length, 2 died for the same dose, and 1 died from 1.3 mg. per cm. It thus seems that avertin with small doses of morphine causes no appreciable reduction, while with larger doses of morphine, a measurable reduction is evident.

In the case of sodium amytal, of 6 dogs receiving intravenously from 28 to 45 mg. per kg., all died from doses ranging from 1 mg. to as low as 5 mg. of procaine per cm. spinal length. It is thus seen that sodium amytal in effective narcotizing

doses causes a marked reduction in the lethal dose of procaine.

The finding, that a barbituric acid derivative reduces the lethal dose intracisternally of procaine hydrochloride, is apparently at variance with the work of HofVendahl,18 Tatum, et al,10 La Mendola14 and Martin and Meyers,15 who showed that members of the barbitutric acid series raise the minimum lethal dose of cocaine administered subcutaneously. The discrepancy, however, is more apparent than real. In cocaine poisoning brought about by the systemic administration of cocaine, the convulsive phase is the striking feature, whereas in injection into the cisterna magna, the paralytic phase is predominant. The works of Jacobj and Roemer, ¹⁶ Impens, ¹⁷ Jackson ¹⁸ and Bouckaert, 19 showing that the barbitals in large doses have a depressing effect on respiration, explain the increased vulnerability to procaine of animals narcotized with sodium amytal.

This lowering of the lethal dose of procaine injected intracisternally by the previous administration of barbituric acide derivatives possesses practical significance in view of the increasing tendency to use them as "basal anaesthetic" in cases of spinal anaesthesia. According to our findings, it is distinctly contra-indicated, and is a misapplication of the findings of HofVendahl, Tatum and others.

The Effect of Some Pathologic States on the Minimum Lethal Dose of Procaine Intracisternally

We have so far conducted only five experiments in this series but expect in the near future to be able to report more extended work. Of the five experiments, three were on animals with distemper, which was taken as a representative disease in the dog and two were on animals that had post-operative peritoneal infection. Tables III and IV show that in both distemper and post-operative peritoneal infection, the minimum lethal dose is appreciably reduced.

Measures of Resuscitation in Respiratory and Vasomotor Center Paralysis

The record of one such an experiment will be set forth as representative. A 20 kilogram dog was given 60 milligrams of procaine hydrochlo-

ride at 4:45. Respiratory paralysis and a steady decline of the blood pressure soon set in, no asphyxial rise having occurred. Artificial respiration was instituted 30 seconds after respiratory stoppage, but the blood pressure continued to fall finally reaching about 5 millimeters. At 5:08, 23 minutes after the injection, 30 milligrams of ephedrine sulphate was injected into the femoral vein; after a latent time of 38 seconds, the blood pressure started to rise until at 5:14 it was above normal. At 5:33 artificial respiration was discontinued to determine if the respiratory center had recovered. Such interruptions of the artificial respiration were repeated at 5:43 and 5:53, but recovery had not yet taken place then. At 5:58. 1 hour and 13 minutes after the injection, artificial respiration was again discontinued, and in a little over a minute, both the intercostal and diaphragmatic breathing recovered spontaneously. At the end of the experiment, therefore, the dog was, to judge from the respiratory and blood pressure tracings, as well as it was when the experiment started.

Summary

1. Respiratory stoppage due to paralysis of the respiratory center does occur when procaine is introduced into the subarachnoid space in sufficient dosage.

2. This dosage is not a fixed one but varies with different body states. Some narcotics and disease conditions make the center more sensitive to the paralyzing effect of procaine. The statement often made that spinal anaesthesia is perfectly safe in bad risks is not confirmed by our

experimental work.

3. When complete paralysis of both the respiratory and the vasomotor centers occurs, artificial respiration and the intravenous injection of ephedrine are effective as measures of resuscitation. Hospitals in which spinal anaesthesia is employed must be prepared to combat with paralysis of the medullary centers; that is, an artificial respiration equipment and measures for sustaining blood pressure, must be at hand.

This work represents one phase of the survey on local anaesthetics in progress at the New York University Division of the Bellevue Hospital under the supervision of Professor George D. Stewart and Dr. Arthur M. Wright.

Grateful acknowledgment is made of the kind permission given by Surgery, Gynecology and Obstetrics for

the use of the material appearing in our article "Experimental Studies on Subarachnoid Anaesthesia" published in the September, 1932 issue, of that journal,

RESUSCITATION

By PALUEL J. FLAGG, M.D., NEW YORK, N Y.

Comments preceding a demonstration of equipment and motion pictures of technique of resuscitation. Given at the Annual Meeting of the Medical Society of the State of New York, at Buffalo N Y, May 25, 1932

T is a pleasure to have an opportunity to disenss with you modern scientific methods of resuscitation now available to the physician.

While our heartiest tribute is extended to the well organized work of the rescue squads, working under the direction of the police department, fire department, the various gas and electric compames, the Red Cross group and the life savers, working under the direction of the Federal Government, nevertheless, we must grant the limitations of this lay personnel in the treatment of these dramatic medical emergencies, and bestir ourselves to awake an enthusiasm for the assistance which the physician can, alone, provide

The first problem in the treatment of cases of asphyxia is, to make known, in a form easily recognizable by the layman, the various degrees of asphyxia which present themselves for relief. Asphyxiated patients readily divide themselves into two large groups.

First, the depressed semi-conscious patient who can be roused; secondly, the unconscious asphyxiated patient who cannot be roused

The first group responds to the stimulation of the prone-pressure Schaffer treatment with or without the use of an inhalator. The second group is distinctly a medical problem requiring the energetic services of the physician

This group of unconscious asphyxiated patients may, furthermore, be divided first, into those patients, who, while asphyxiated and unconscious, are breathing, even though irregularly. whose muscles are fixed in spasm, whose reflexes are active, and whose eirculation is fairly well Secondly, into the desperately ill maintained. patient who has become apnœic, who is completely relaxed, whose reflexes are in abeyance, and whose circulation is rapidly failing

The first of these two classes requires the assistance of a physician in order to prevent the progression of the asphyxia into the second class This is likely to occur as respiratory obstruction from masseteric spasm or from foreign body obstruction gives rise to a vicious errcle ending in apnœa and complete relaxation,

Such patients, since they are breathing, will frequently be rescued by the use of an inhaler delivering oxygen and CO2 Where respiratory obstruction is marked, reducing the tidal volume breathed to such an extent that oxygen and CO2 is not inhaled in sufficient volumes to relieve the aspliyxia, then it becomes necessary to introduce this gas past the obstruction by means of a pharyngeal tube, where the teeth may be separated to permit this, or by the use of a nasal tube, in cases of severe spasm. This procedure, if promptly instituted, will usually relieve the patient

Our interest, as physicians, however, is particularly directed to the second group of unconscious patients, the patient in extremis, the patient who has been referred to, as the apparently dead Owing to the fact that in extreme asphysia the chest is fixed in a position of expiration, lit-He or nothing can be hoped for from prone pres-

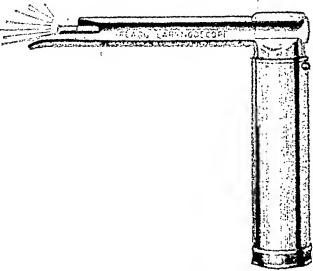

Fig. 1. The Laryngoscope

sure methods with or without the use of an Such a patient can only be revived by the insufflation of oxygen and CO2 under measured pressure directly within the trachea.

Fortunately, the condition of such a patient, namely, the absence of muscular rigidity and reflexes, permits of direct treatment without trauma.

Complete asphyxia is not an infrequent occurrence. It is seen, occasionally, during the complete relaxation which accompanies anesthesia, the anesthetist being suddenly faced by such an apparently dead patient. When ether, the safest general anesthetic, has been employed ,resuscitation will be successful, as long as the circulation is still functioning. These apparently dead patients occur with regular frequency in the newborn to the extent of at least one in every hundred.

It is believed that death may be pronounced where there is no change in the color of

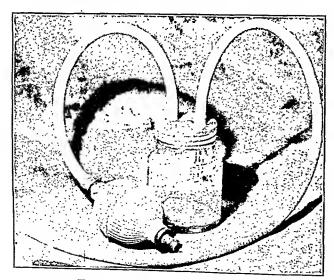

Fig. 2. Flagg Portable Suction

an asphyxiated patient after intratracheal insufflation of oxygen under pressure over a period of five minutes. A constant cyanosis, under these conditions, is proof that the heart no longer beats. and that the circulation has ceased.

Aside from the life-saving value of such technique, the economy, in the gases consumed, and the labor of a squad for hours after a patient is dead is a worthwhile consideration.

The instrumentarium assembled, and the technique described is designed to meet the requirements of the extremes of age and anatomical variations, as well as asphyxia from every possible cause, such as anesthesia local and general, drug poisoning, foreign body obstruction, asphyxia neonatorum, submersion, electric stroke, carbon monoxide poisoning, etc. The equipment is adapted to operating-room and ambulance use.

The instrumentarium consists of laryngoscope, suction facilities, intubation tubes, and a gas supply under regulated pressure.

The laryngoscope (Fig. 1) is a strong onepiece instrument with a large light, powered by small cells procurable anywhere. This is available in three sizes.

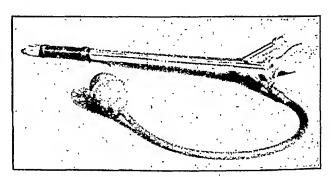

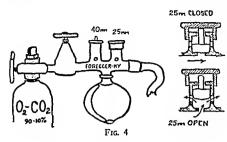

Fig. 3. Intubation Tubes

Portable suction (Fig. 2) will take care of most emergencies. For ambulance use, connection should be made with the intake manifold of the gasoline engine, where abundant suction is available.

For operating-room use, steam, or electric suction is routinely available; steam suction being always preferable because of its quiet, powerful suction with no parts to get out of order. It is inexpensive to install and to maintain. equipment is now available through commercial channels.

The intubation tubes are made up for infant use, and for the resuscitation of the adult (Fig. 3). The infant tube is of such a length and such a diameter that it may not be introduced past the corina. It has a velvet, non-trumatic tip. adult tube is a typical bronchoscope reduced in length to prevent its introduction into a bronchus. An extremely valuable accessory to this tube is a rubber balloon which may be distended after intubation, thereby allowing full control of the

intra-pulmonary pressure. All of the intratracheal tubes are operated by simply closing a vent at the proximal end to produce inspiration, opening it to allow expiration. This is the only manipulation required in the use of these tubes.

The gas supply, consisting of an oxygen and CO₂ mixture—90% oxygen and 10% CO₂—is available in small cylinders, under a pressure of from twelve to fifteen hundred pounds. This

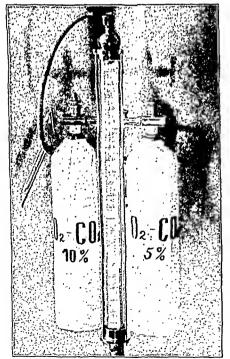

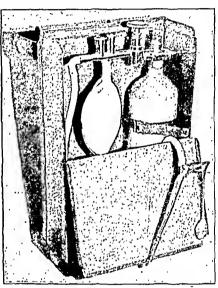

Fig. 5. The Flagg Hospital Resuscitation Apparatus

pressure, released by a reducing valve, is delivered to the patient with the added protection of a pressure manometer which may be set to accurately measure the pressure at which the gas is delivered. For operating-room use, where delicate adjustment is desirable, the water manometer is the manometer of choice. Water pressure is translated into mercury pressure, as follows:

The specific gravity of mercury is thirteen; water is one; there are twenty-five millimeters to the inch. If we consider an inch as twenty-six millimeters for purposes of easy measuration, one-half inch of water would equal thirteen millimeters, or one millimeter of mercury, and

F16. 6. Resuscitation Apparatus for Ambulance

one inch of water would equal two millimeters of mercury. Therefore, a column of water twelve and one-half inches deep would equal a mercury pressure of twenty-five millimeters. The water manometer is preferred because it indicates the volume flow of gas, shows any aspiration effect, and affords protection against pressure. For use in emergency work in the ambulance, or elsewhere, a weight manometer acts as a safety valve (Fig. 4). This valve is constructed so that it will blow off at twenty-five or forty millimeters, as desired; the maximum pressure for adults being forty millimeters, and that for infants, twenty-five millimeters.

The volume of the gas delivered is regulated according to the rapidity with which one wishes

to bring about insufflation. This volume varies from two to ten liters a minute. Where a balloon tube is used, there is little necessity for a large volume delivered.

Figure 5 shows the author's hospital rescusci-

tation equipment with a water manometer.

Figure 6 is a rescuscitation assembly for ambulance use.

TECHNIQUE OF APPLICATION

The asphyxiated patient is immediately laryngoscoped. The mere act of laryngoscopy, by raising the soft parts and freeing the air-way, often

relieves the asphyxia.

Foreign bodies, fluids, etc., are promptly removed by suction. The intubation tube is then quickly introduced. The introduction of this tube immediately renders effective manual pressure upon the chest, which may be in progress (Sylvester). If the balloon tube of Coryllos is used, the balloon is now distended, and the oxygen (CO₂) connected; the vent of the intubation tube is then closed by the thumb, and is held in this position while the lungs are distending and until the manometer begins to blow off, at the pressure for which it is set. Insufflation is repeated at intervals of about sixteen times a minute. Upon the first evidence of voluntary respiration, the patient is allowed to breathe through the tube, his respiration being encouraged by an occasional insufflation, or by partly closing the vent of the tube. When the laryngeal reflexes have become active, the balloon is decompressed, and the intratracheal tube is withdrawn. From this time forward, any further depression in the respiration may be satisfactorily met by rebreathing oxygen CO₂ through a pharyngeal tube, or from an inhaler.

COMMENTS

Of the methods available for resuscitation, the only method offering hope of recovery, in the case of extreme aspliyxia, absent respiration, absent reflexes, complete relaxation, and failing circulation, is intratracheal insufflation of oxygen carbon dioxide, under pressure, because this technique, alone, fulfills the three urgent and essential requirements for asphyxial relief:

First, anoxemia is overcome by the highly concentrated oxygen thrown directly into the absorbing area; the respiratory center is stimulated by the specific action of carbon dioxide; and, finally, the Herring-Breuer reflex is directly stimulated through the physical distention of the chest by

the insufflated gas.

In the case of the newborn, an additional vital benefit is conferred by the relief of ante-natal atelectasis.

Annual Meeting, April 3-5, in the Waldorf-Astoria, New York City,

ORGANIZED MEDICINE

The modern practice of medicine demands an almost contradictory combination of individualism and cooperation among physicians, so that today the medical society is as essential as the family doctor. Scientific physicians everywhere adopt uniform standards and methods which are determined and expressed by their medical societies.

The community, too, in distinction from the individual patient, is developing standards and methods for cooperating with the medical profession. The part to be taken by lay agencies, both voluntary and governmental, in the practice of medicine will be a basic subject for discussion in the coming meeting of the Medical Society of the State of New York.

FEATURES OF THE ANNUAL MEETING

The last issue of this Journal—that of March first—was almost entirely on the subject of the annual meeting, seventy-four pages being with the annual reports, the programs of the events, and descriptions of the exhibits and other features of the meeting. This issue contains some final announcements, beginning on page 408.

The wealth of features for which careful preparations have been made will insure unusual satisfaction to every physician that attends the meeting. For those who come early on the opening day, Monday, April third, there is a choice of clinics in twenty-three hospitals listed in the last Journal, beginning on page 326, so that a visiting member may be profitably occupied from nine in the morning to half-past five. But many will wish to attend the sessions of the House of Delegates and the dinner in the early evening.

The most serious appeal of a State Society meeting is that of the scientific sessions. Members not only wish to hear papers which will aid them in their practice, but also they wish to see the speakers, especially the guests who have been specially invited to deliver lectures. The Scientific Program which was printed in the last Journal, beginning on page 319, listed 87 subjects to be presented by 178 physicians, in addition to unlisted discussants, among whom any member is privileged to be numbered. Surely this is a professional feast suited to every taste and digestion.

The visiting member will be well entertained and instructed if he spends all day Tuesday and

Wednesday in the scientific sessions; but as he passes from one meeting room to another, he will do well to pause for a study of the Scientific Exhibits, of which 48 are listed on the last Journal, beginning on page 325.

The annual meeting will have a social appeal in the Banquet on Tuesday evening. Members are expected to bring their ladies and to entertain them afterward at a Dance, which is scheduled to continue until two o'clock in the morning. While the after-dinner speaking will technically constitute *The Annual Meeting*, it will also demonstrate the amenities of the professional life of the doctor.

Wednesday evening will be given over to the public so that the prospective patients may hear what the doctors expect them to known about professional matters. This meeting will be of interest to those physicians who are engaged in the new practice of public health education.

A doctor must have medical equipments and supplies, which he will find demonstrated in sixty booths which are listed and described in the last Journal, beginning on page 332.

Finally there are the unlisted opportunities to meet one's colleagues in the assembly rooms, along the corridors, and at the dining tables. Probably the events which will arise in memory the most frequently will be those of casual conversations with friends, both new and old. The inspiration of their personalities will be the greatest influence of the annual meeting.

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO

Functional Nervous Diseases: This Journal of March, 1908, comments on functional nervous diseases as follows:

"Joseph Collins, in a recent article, makes the statement that nervous diseases, contrary to the general tradition, yield more uniformly to treatment than any other class of diseases of comparable nature and severity. Nor is a correct diagnosis necessary for the successful treatment of many neuroses. While this is not in abrogation of the necessity for correct diagnosis, still it has a very practical bearing upon the results secured by faith curists, Christian Scientists,

shrines, systems, osteopaths, and charlatans innumerable. What these people have been able to do without diagnosis has been decidedly suggestive and helpful to the science of medicine. Pretense and fraud have taught medicine some valuable lessons. Collins is opposed to the claim that no one but the neurologist can treat nervous diseases; the general practitioner should study the proper manner of treating them with the same care that he studies infant feeding or the treatment of typhoid. These patients are sick and are entitled to better treatment than being told that there is nothing the matter with them."

Ø.

MEDICAL PROGRESS

The Medical Treatment of Spastic Conditions,-Despite the well founded scientific basis for the use of papaverine to relieve spastic conditions of the smooth musculature, says Hanns Löhr, writing in the Münchener medizinische Wochenschrift of December 23, 1932, papaverine administered alone has never been able to secure a foothold in medical practice. This is due possibly to poor results from underdosage, or possilly to individual sensitivity to the medicament. On account of the wide variety of therapentic effects exhibited by papaverine, Löhr has been trying for the last 6 years to place its therapeutic action upon a firmer basis by combining it with atropine and barbituric acid. By a combination of atropine 0.0005 gm., papaverine 0.025 gm. and diallylbarbituric acid 0.02 gm., he has produced a preparation which has given remarkable results in the prevention of spastie states of the smooth musculature. The advantage of this combination lies in the fact that by adding small amounts of barbituric acid, the usual dosage of atropine and papaverine can be reduced without loss of efficacy, thus preventing the secondary effects frequently observed from atropine. Gordonoff in 1931 demonstrated in the laboratory that this combination has an effect of high potency in relieving spasms experimentally produced, thus confirming the clinical results already obtained by Löhr. The latter having observed its excellent effects upon the gastrointestinal canal, has now extended its use to spastic conditions of other hollow organs, such as biliary and ureteral colics, and has found the results equally gratifying. He has also observed far-reaching symptomatic improvement in bronchial asthma and angina pectoris. rectal use of the preparation in the form of suppositories is advantageous in spassus of the kidney, ureter, and bladder, in which vomiting is so common as to make oral administration useless. The preparation is promptly reabsorbed into the blood stream through the hemorrhoidal and hypogastric veins, without having first to traverse the The suppositories are also indicated in dysmenorrhea and in the bladder tenesmus of acute pyelitis and cystitis, in which they have a definitely soothing effect.

The Control of Coughing.—The importance of knowing how to prevent attacks of coughing by controlling the function of the larynx is pointed out by Paul Lohfeldt in the Deutsche medizimische Wochenschrift of December 23, 1932. In the act of coughing, as is well known, the larynx is closed airtight and then opened explosively, while the air that has been placed under pressure by the closure suddenly escapes. There

are two ways of hindering this escape: 1st, by preventing the larynx from closing, and 2nd, after it is already closed, by refusing for a time to let it open. When the impulse to cough is not too great, the first end may be gained by the simple device of pronouncing a toneless S, for in every such act the larynx opens or remains open. Another way, if the urge to cough is greater, is to draw a large number of very short breaths in close succession, comparable to the panting of a dog. so that the larynx does not have time to open during the expiration or between inspiration and ex-The coughing reflex is thus offset by piration. the stronger breathing and opening reflex. The cough can also be suppressed by making strong pressure against the airtight closure of the larynx, but this requires strong will power and much practice, the aim being to restrict the cough to the very slight push necessary to expel the muens that has collected below the larynx. There is a tendency to cough much too soon and therefore far too much, before the mucus has loosened its hold, which it will do more quickly and amply if the patient learns to repress the cough until the right moment. Not only do cough sufferers make the mistake of coughing too much, but they also do not cough correctly. The patient must be educated to breathe deeply when the mucus loosens its hold spontaneously and nears the outlet, then to open the larynx suddenly to its maximum and drive the air through it with a long, unbroken pull. It is similarly possible to control clearing of the throat, and thus to avoid unnecessary rasping of the larynx, Improving and strengthening the voice with special reference to the relief of laryngeal tension is to be recommended. Many individuals have, through coughing and clearing the throat, lost the function of correct full closure of the larynx, and this is often connected with disturbances of the voice, the correction of which by proper training may do wonders for the control of fits of coughing.

Necrotizing Arteritis and Subacute Glomerulonephritis in Gonococcic Endoarteritis.—Milton Helpern and Max Trubek, writing in the Archives of Pathology, January, 1933, xv, 1, state that there is a question whether the lesions usually designated as periarteritis nodosa are caused by a specific bacterial agent or virus, or whether they represent a specific vascular reaction to any of the great variety of toxic agents. They report a case which strengthens the conception of the nonspecific toxic origin of these lesions. The patient died from uremia with pericarditis, following a subacute glomerulonephritis of ten weeks' duration. This illness started eight weeks

after a gonococcic urethritis complicated by gono-At necropsy, a right-sided coccic ophthalmia. subacute gonococcic endocarditis of the pulmonic valve and a typical subacute glomerulonephritis were found. In addition, isolated inflammatory lesions of the small arteries were found in two widely separated regions of the body, namely, the choroid coat of the eye and the testis. The histological features of these lesions conform to many of those which are characteristic of periarteritis nodosa. Thus, medial fibrinoid necrosis, disintegration of the elastic interna, subendothelial intimal proliferation resulting in fibroblastic obliteration and canalization of the lumen, vacuolation of the endothelial cells, excentric involvement of the vessel walls, absence of suppuration and the occasional periarteritic nodule were present. The larger arteries of the body were not involved, and the distribution of the lesions was not extensive enough to produce clinical manifestations. The renal lesion represented a severe reaction of a sensitive organ to the toxin produced by the gonococci growing on the pulmonic valve. The vascular lesions, which were anatomically dissociated from the kidney, were also considered a specific reaction of sensitive vessels to this same toxin. The findings in this case, the authors believe, strengthen the conception that these vascular lesions and those of periarteritis nodosa do not represent a specific disease, but rather a specific reaction of the blood vessels to any of a whole group of variable toxins.

Swineherd's Disease.—A report on 15 personal cases of this curious fever, observed within 2 years, is made by Eugène Urech in the Schweizerische medizinische Wochenschrift of January 14, 1933. All the patients were young swineherds, employed as apprentices in dairies. Only one of them had exercised his calling for more than a short period of time, and in no case had they come from farms, although the raising of hogs is a common occupation among the peasantry of the Canton de Vaud. The temperature curve is characteristic: after an afebrile prodromal period of 3 or 4 days the fever rises to 39° or 40° C., where it oscillates for 4 days, dropping by crisis on the 5th day, only to rise again 12-24-48-60 hours later, in an absolutely constant wave lasting 24 to 48 hours, this time rarely exceeding 39°. After a second crisis convalescence ensues of an easy type entirely different from the laborious convalescence from grip. The pulse curve indicates a clear dissociation between pulse and temperature. clinical symptoms are much less characteristic, beginning more or less like those of typhoid or a severe attack of grip, without focal lesions, although certain abdominal symptoms attract the attention at once. Prostration intense headache, and sometimes profuse sudor are frequently conspicuous, attended or not by delirium with bradycardia. Some of the patients exhibited albu-

minuria and hematuria for a few days. Lumbar puncture revealed nothing abnormal. Two patients had an urticarial eruption for 5 days, and somewhat more frequent was a buccal enanthem with hemorrhagic patches, often confluent. The blood count revealed a maximum of 12,400 white cells in the patient most profoundly affected, with a relative polynucleosis of 70 to 80 per cent. Red cells often exceeded 6.000,000. No eosinophils were present. Lasting immunity seems to follow the affection, no recurrence having been observed. Apparently the disease is not contagious from man to man. It is very probable that it is transmitted by hogs or milk (cheese, butter), but the precise cause still eludes discovery, despite extensive laboratory research. The clinical picture recalls those of dengue and pappataci fever, the temperature curve being the same for the three The two latter are transmitted by an intermediate host, and the question arises whether the same is not true of swineherd's disease.

Skeletal Traction with the Steinmann Pin.-Merrill K. Lindsay and Raymond M. McKeown state that fractures of both bones of the leg in its lower two-thirds are observed with greater frequency as traffic accidents increase, while the difficulties involved in their treatment still remain a problem. Up to the present time the pin has been used with reluctance owing to a widespread belief that the procedure is not without considerable danger. During the past five years the authors have treated 52 cases of fracture of both bones of the leg with Steinmann pin skeletal traction. In no case have they had either perceptible necrosis or osteomyelitis of the calcaneus through which the pin was inserted. The alignment has been satisfactory without appreciable shortening, and functional union has likewise been satisfactory. The procedure is not difficult, if a few simple principles are observed. The point of introduction of the Steinmann pin into, and through, the calcaneus is of primary importance. Blood-vessels and tendons must be avoided, and the line of traction must be in the long line of the leg. This is best secured with the foot in neutral position and right-angle dorsiflexion. A point which meets these requirements is found 1 cm. posterior and distal to the trochlear process of the calcaneus. The skin is prepared by the application of benzine, ether, and tincture of iodine, the iodine being removed by sponging with alcohol. Using the landmark indicated above, a skin incision 1 cm. in length is made in the long axis of the limb. Before incision the skin is drawn slightly toward the external malleolus, so that most of the incision will be distal to the point selected for inserting the pin, when the skin is subsequently released. With a hand drill or brace the pin is driven through the calcaneus at a right angle to the long axis of the tibia, until it can be felt beneath the skin on the medial aspect of the calcaneus. A second skin

meision is then made, to permit the pin to pass through The traction calipers are attached to the ends of the pin, and the traction rope temporarily fastened to the ends of a Thomas splint The skin at its points of contact with the pin is protected with alcohol dressings The patient is returned to bed, and traction of from 10 to 20 pounds, as the ease necessitates, is applied with the leg in the Thomas splint in balanced suspension from a Balkan frame. After twenty four hours the position of the fragments is checked by a ray examination By the fourth or fifth week the pin can be removed and a long plaster boot from the mid thigh to the tip of the toes is then applied, with sufficient flexion at the knee to prevent rotation Three or four weeks later a Delbet of the leg splint is substituted and active motion of the knee and ankle is started -Surgery, Gynccology and Obstetries, February, 1933, Ivi, 2

The Meltzer-Lyon Test and Cholecystography in Affections of the Biliary Tract-A systematic comparison was made by Domenico Santorsola and Vincenzo Gandolfi of the findings resulting from cholecystography and from the Meltzer Lyon test in a series of 22 eases In 10 eases both methods showed negative results, that is, there was no visibility of the gall bladder in the radiogram, no flow of B-bile in the duo denal test. In the first 9 of these eases operative results confirmed the presence of such lesions of the gall bladder and of the cystic and common duets as could leave no doubt of their impaired function. In 1 case where operation was impossible owing to the poor condition of the patient, the elimical symptomatology supported the diagnosis of grave cholecystitis. In 10 more eases the two methods were in agreement as to the presence of normality, in 5 of these the results were confirmed at operation, in the other 5, not operated upon, the clinical symptomatology and liter observations made it possible to exclude lesions of the biliary tract. In only 2 of the 22 cases were the results of the two methods at variance. In one of these the presence of an enormous echinococcus exist of the liver was a sufficient justification for an abnormal cholecys tograpluc result In the other ease, in which despite the presence of adhesions, the opaque substruce could be concentrated in the gall-bladder by a residuum of function, and in which the walls showed no considerable lesion in the cholecystogram it is probable that the gall bladder, a prey to inflammatory processes was not in a condition to respond to the stimulation exerted by the sulphate of magnesia The authors are satisfied that both methods should be regarded as dependable tests of gall bladder function, and that their association in practice may reveal, better than either alone functional disturbances which are the index of auttomic lesions of that organ. The cholecystogram does not always reveal with precision those changes which have but slight reper cussion upon the organ's function, and to base a judgment solely upon the intensity, uniformity, and clearness of the sliadow is unsife. On the other land, there are cases in which the Meltzer-Lyon test cannot be mide, owing to the patient's intolerance or to annionic or functional changes of the stomach or diodenum. When, however, the test succeeds, as is usually the case, a comparison of its findings with those of cholecys tography may throw a clear light upon the significance of the results of the latter—Riforma medica, December 10, 1932.

Mumps and Appendicitis -In an article en titled "An Unusual Case of Epidemic Mumps Complicated by Gangrenous Appendicitis," published in the Archives of Pediatrics, Maich, 1932, Sandler and Tinne state that only five examples of this combination of diseases have been described in the literature James Donnelly and James Bagot Oldfinn writing in the British Medical Journal, January 21, 1933, 1, 3759, re port the following ease. On May 25, 1932, a boy, aged 7 years, was seen by one of the authors and found to be suffering from mumps, to which he had been exposed a week previously On May 29th the boy seemed to be convalescing well That evening he complained of pain in the epigastrum, vomited and became restless The tem perature rose to 100° F, the pulse rate was 90 On May 31st the temperature was 100° and the pulse rate had risen to 98 The epigastric pain had diminished, but tenderness and rigidity had increased. The next day these symptoms were more marked, but there was very little pain diagnosis of acute appendicitis was made and an operation was performed. A large quantity of thin, purulent, slightly offensive fluid gushed out of the meision, and it was found that the whole lower abdomen and pelvis were involved in peritonitis The appendix, which was gangrenous and perforated, was removed. Colvalescence was uneventful The details in this case correspond very closely with those of the cases reported in the literature As is well known, orclutis is a very common complication of mumps, and usually occurs about the eight day Less commonly ovaritis, mastitis, pancreatitis, and enlargement of Bartholm's glands are reported. It is generally admitted that these complications are metastatic infections arising from the primary foci in the parotid glands. Is appendicitis another possible complication of inumps of is their association simply a coincidence? In all the cases thus far reported, the onset of the acute appendicitis has occurred a week or thereabouts after the parotitis started

Free Iodine in the Treatment of Vasomotor Rhinitis and the Symptom Complex of Sneezing and Nasal Hydrorrhea—In a preliminary report Morris Levine describes encouraging results in the treatment of vasoniotor rhinitis, the common cold, and hay fever with subcutaneous injections of a 5 per cent iodine solution containing traces of free iodine. He points out that, although of diverse etiology, vasomotor rhinitis, the common cold, and hay fever have one pathological finding in common, namely, a waterlogged condition of the nasal mucosa. Pharmacologically, it has been established that iodine is eliminated in part by the mucous membrane of the upper respiratory tract, upon which it has a definite stimulating action. From the prompt relief afforded in cases of nasal hydrorrhea, whether due to infection or allergy, it would appear that its influence is principally upon the aqueous metabolism to relieve a water-logged condition. date Levine has treated 20 cases of pure vasorhinitis and 50 of a mixed type. Injections were given every two or three days until the symptoms subsided completely. As a rule about six injections were required; in the more obstinate cases as many as ten. Without exception relief was experienced after two or more injections. The preparation used was iodomin, supplied in 1 c.c. ampules, and even children three years old have tolerated a full ampule without harm. In a series of 20 cases of common cold the injections gave early relief from sneezing, nasal stuffiness and watery discharge, but the results were not so gratifying as in vasomotor rhinitis, probably because it is difficult to see patients in the very beginning of a common cold. Laryngitis is a definite contraindication to the use of iodomin, because of the possibility that such patients may develop edema of the larynx on iodine medication.—Laryngoscope, January, 1933, xliii, 1.

The Little Known Eutrophic Action of Hypodermic Oxygen Therapy.—An attempt was made by J. Jarricot to check up a recent statement of Briand (1929) that children injected hypodermically with oxygen during the course of an epidemic of whooping cough had undergone no loss of weight but had, on the contrary, put on extra weight, suggesting that oxygen thus administered exerts a stimulating effect upon the nutrition of the child. The question is also related to Heckel's observation that injections of oxygen have a retarding effect upon obesity. Jarricot's own work in this field has been to assemble, by careful selection, a homogeneous group of 63 hypotrophic infants (15 to 30 per cent under weight) and subject them to a uniform treatment, an identical nutrition, the same surveillance and the same tests (3 weighings a week), then to compare their growth during the first month of observation with that during the second, the only difference between the two months being that in the second month the children received 3 or 4 injections of oxygen per week hypodermically, of 100 to 200 c.c. each. It is to be noted that the injections were not made for experimental purposes, but solely because of therapeutic obligations to children in whom impaired health (anemia, cough, etc.) demanded supplementary treatment. Children with whooping cough were definitely excluded, in order that the issue might not be clouded by the improvement in the general condition that results naturally in the course of the disease when vomiting disappears. It was found that only 17 children exhibited the same rate of growth during the 2 periods (3) or a deficiency of growth in the 2nd month (14); and such deficiency was only relative after all, the average daily growth in these 14 infants having been 29 gm. in the 1st month and 18 gm. in the 2nd. In the other 46 infants the growth was superior during the 2nd month, with a daily average gain of 23.5 gm. against 9 gm. before the injections began. Hence it appears that oxygen administered hypodermically exerts a cutrophic action, at least in young children.—Bulletin de l'Académie de Médecine, December 20, 1932.

Dysentery as a Cause of Sudden Death.— Eileen Harvey, writing in The Lancet, January 28, 1933, ccxxiv, 5709, calls attention to the fact that dysenteric infection may prove so rapidly fatal that there is no time for the development of any symptoms of the disease. She reports five cases, one in a man aged 65 years, one in a male infant, and the others in boys aged three, six, and nine years. The most striking feature on postmortem examination in all the cases was the presence of a ring of lymphoid hyperplasia and edema around the ileocecal valve; this varied in size and extent from case to case. In some it extended for several inches up the ileum and down the cecum. No record of this appearance has been found in descriptions by other workers of postmortem examinations in cases of dysentery. A possible explanation of this discrepancy is that the ilcocecal hyperplasia may be a feature of the most fulminating cases, of which those here reported were examples. Cultures were taken from the mucosa and contents of the bowel at several levels and from the spleen in each case, but 110 microorganisms of any pathological importance were isolated. This may be attributable to the tact that in no case was the post-mortem examination made until the second day, and in some cases not until the third day, after death. dysenteriæ Sonne was isolated from a sister who had been ill at the same time as one of the patients, which makes it likely that in this case the infecting organism was of the Sonne type. Fulminating infection with rapid death due to B. dysenteriæ Sonne does not seem to have been reported before. That death should occur as a result of a dysenteric infection without the appearance of the cardinal symptom of diarrhea, as in two of the cases, does not seem to have been previously noted.

LEGAL

PRIVATE HOSPITALS—CONTROL OVER UNRULY PATIENTS

By LORENZ J BROSNAN, ESQ Counsel Medical Society of the State of New York

An interesting legal situation has arisen in various cases where the question has been brought out as to the manner in which a private hospital may properly restrain its inmates by the use of force There can be no question but that in proper cases the servants of a private institution may be perfectly justified to forcibly suppress the actions of an unruly patient even though the patient is not an adjudged lunatic. Patients who are not in the least insane often suffer from delirium and hallucinations as a result of some non-mental discase and they must be handled with force The opinion of the court in a very recent case recognizes the situation that exists in the handling of patients with nervous disorders. The court in that case said.

"Institutions which receive persons affected with nervous diseases for hire should be supplied with reasonable devices of restraint, such as straps, Jackets, wristlets, anklets, blankets, and other approved apparatus and also sufficient man power to take eare of violent eases, which may develop at the moment, at the least minimum of danger to the patient"

An interesting case recently was taken up to the highest court of one of our Pacific States which well illustrates the type of case where a private liospital may be held accountable in damages for the violent handling of an inmate excitable young Italian, thirty-three years of age, who was robust physically, was preparing to make a trip to Italy His brother became worried about the excited state which he was in and called a doctor to examine the man preparatory to his leaving for the trip The doctor examined him and found him in excellent shape except that he was overexcited and suffering from a minor stomach difficulty The doctor gave him some medicine for the latter condition. He later testified that the patient's case was one of acute neurasthema, but that he was in no way violent The patient's brother watched his nervous state later the same night and called the doctor again requesting that he observe the patient. The doc tor was unable to call at the home of the Italians and requested that the patient be taken to a cer tain hospital where he would again look him The man was taken by the members of his family and left at the hospital He was assigned to a room and a female nurse undertook to assist lum take off his clothes It seems that during his whole life he had been extremely shy and diffident

toward all women except members of his family, and that peenharity combined with his nervous state caused him to become extremely excited. He excitedly and in a loud voice ordered the nurse out of the room. The head nurse of the institution decided that he was a dangerous nervous case, and at her instance the man was taken in a short while to another hospital where he was admitted and assigned to a room. Apparently the whole circumstances of his entry at the said hospital took place under the understanding that he was dangerous, for he was put in a room on a floor set apart for severe mental and alcoholic cases.

Several hours later the man wished to go to the bathroom and called a male nurse who directed the way He had no clothing on but had a single sheet wrapped around him. He suddenly became confronted with a female nurse in the corridor and hecame greatly agitated, shouting, "Don't touch me, if you do, I will kill you" He was thereupon put in a so called "strong room" be hind double-locked doors. In about two hours he suddenly smashed through the panels of the doors, emerging into the coiridor where he demanded some clothes from the first person he saw-a patient A female nurse appeared and he demanded his clothes from her, at which she rang an emergency bell At this the man grabbed the nurse by the arm. In an instant a doctor appeared and the nurse, whom the patient had released, told the doctor that the man should be taken care of The patient apparently became very panic stricken and started hysterically to try to escape The doctor pursued him with an up raised chair and a struggle ensued which lasted a considerable time The doctor was joined by others in an attempt to subdue the patient and finally an improvised tourniquet consisting of a towel was applied to the man's neck and a con siderable amount of ether on a piece of gauze was held over his face As the man's resistance grew weaker someone called the attention of the doctor to the fact that the patient appeared to be exanotic and needed air, but the doctor by that time excited and enraged did not heed the suggestion. When the man's struggle ceased efforts were made to re vive him, which were in vain and he was dis covered to be dead

A suit for damages based upon alleged death by wrongful act was brought against the sanitarium. The defense was that the man's condition justified the use of the methods used to subdue him. The jury, however, found a verdict for the plaintiff and on appeal the court found that the testimony amply supported the verdict. The court expressed itself as of the opinion that the methods of restraint were fraught with too much danger to the patient to be used at any hospital. The case, of course, is an extreme one, but shows that strongarm methods must be used upon unruly patients with great care.

Another case of coercion that came before the courts, presented on the testimony a startling set of facts. A nervous young woman, who had been suffering from malaria and who needed rest, entered a private hospital for a period of recuperation. The day after her admission she was told by nurses that the doctor in charge had ordered her breasts massaged and her hair shampooed. She protested against the treatment, saying that her hair had just been shampooed before entry at the institution and that her condition was too delicate for her to be massaged. The nurses, however, forcibly administered the treatment against her will. She then demanded that she be permitted to leave the place and to see her sister. The doctor in charge refused to grant either request. At that the girl announced that if they continued to refuse she would jump out of a window. Thereupon she was placed in a padded cell behind bars. Adjoining this were raving lunatics continuously shrieking. She was kept in the said place for five days and then removed to another room where she was restrained of her liberty and prevented from communicating with her family. According to her testimony, during this period of confinement she was forcibly subjected to numerous compulsory hypodermic injections and she was roughly treated upon various occasions when she was being taken from place to place about the sanitarium. She was held for over three weeks in all, until she finally managed to send a note to her mother by bribing a servant. Her release was obtained and suit brought against the proprietor and the hospital to recover damages for unlawful detention.

The defense was that she was a nervous case and required restraint and that she could not be set at liberty without danger to herself, and further that she had upon admission subscribed to the rules and regulations of the hospital. The further defense was that all that transpired had

been done in good faith on the part of the sanitarium and those in control, in the belief that she was not mentally capable of caring for herself. The doctor in charge of the place testified for the defense that the patient had suffered from lack of self-control amounting to hysteria. He did not claim that she was insane, but described her condition of hysteria as being "the borderland between sanity and insanity." However, a verdict was found in favor of the patient which was affirmed upon appeal. The appellate court in its opinion discussed the relation between the parties as follows:

"The plaintiff was not committed as insane, and if she had been the defendants do not account for the fact that they accepted her as sane by signing the agreement with her upon her entrance into the institution. If she subsequently became insane, it was the duty of the institution to have at once notified her mother and sister. The testimony of the defendants, however, is that she was not insane. Evidently, the defendant C believed that he had absolute control of the plaintiff and the right to imprison her if she opposed his orders or will, and the right to impose on her whatever treatment he thought best, and that the family need not be consulted any more than the plaintift herself. The effect of being the head of such institution is very often-too often-to render the person in charge callous and autocratic, and in his own opinion irresponsible to anyone.

"In this land the law guarantees liberty to every one, subject to restraint only in the modes provided by the law, and even then there is the right to review the conduct of those in charge of those deprived of their liberty. The plaintiff was not committed to the care of the defendants by any legal proceedings adjudging her insane, and her signing the paper agreeing to be subject to the rules and regulations of the institution was not irrevocable. It did not subject her to the irresponsible power and control of the defendant....

"If the plaintiff did not abide by her agreement to obey the rules and regulations of the institution the remedy of the defendants was to discharge her, or if her condition forbade this, to notify her relatives (neither of which they did), and not to imprison her and to force her to do their will."

While these cases are somewhat extreme as to the facts and situations, they illustrate the abuses that can exist in the handling of nervous cases.

GLAUCOMA FOLLOWING TREATMENT OF EYES

A doctor who was engaged particularly in the treatment of the eye, went away from his office for an extended trip and made arrangements with another eye specialist to occupy his offices during

his absence. The arrangement was merely that the second doctor should be available to treat his own private patients and to treat such patients of the first doctor who might request his services. One of the first doctor's old patients called and decided to see the second doctor with respect to an examination for glasses. The doctor after he had placed a drop of homatropine and eocaine in each eye, examined her and found a far sighted astigmatism. She was told to return in a few days but did not do so. About the fifth day, however, the doctor received a call to her home and found her complaining of headaches and pain in one eye. The doctor prescribed medications and after a few days had elapsed during which time the patient remained under the doctor's care he made a definite diagnosis that a condition of glaucoma existed affecting the right eye. The doctor gave her continued medical treatment but the condition did not improve, so after several weeks the doctor referred her to another eye surgeon who performed an iridectomy upon the eye. The result was a partial improvement only.

Suit was brought against the doctor who treated the patient and also the doctor whose patient she had been on prior occasions. The complaint against the latter was based on a theory of agency,

The charge was that the negligence of the defendants had caused the complete loss of one eye and partial loss of the other. The case came on for trial and the plaintiff tried to make out a case on the elaim that when she had come in for examination she had been suffering from a condition manifested by dull headaches, blurring of vision and faulty vision in that illuminated objects appeared to be surrounded by rainbow-like rings. The testimony was that the doctor was told of said symptoms and that in the face of them he administered to the patient atropine. The doctor denied ever having received any such history, or having administered atropine. The trial proceeded to the point when the plaintiff's testimony had nearly all been introduced and an expert witness put on the stand on behalf of the plaintiff was being crossexamined. The plaintiff's attorney apparently realizing that the case had not progressed favorably for his side, stipulated in open court to discontinue the action and escape the possibility of a judgment for costs, thereby terminating the matter.

ALLEGED NEGLIGENT ADMINISTRATION OF DIATHERMY TREATMENT

An elderly woman consulted a physician who was specializing in orthopedic surgery at a hospital elinic conducted by him, complaining of inability to properly use her left arm and stiffness of the fingers of her left hand. The doctor examined her and diagnosed her condition as synovitis, complicating a chronic adhesive arthritis of the left shoulder joint. The doctor advised diathermy treatments, which were administered to her, and some time later he gave her certain intravenous injections of sodium bicarbonate.

After the patient had continued under the doctor's care for two months, receiving such treatments, and her condition had not greatly improved, he had the patient admitted to the hospital for further treatment. He put her under a general anesthetic and manipulated the arm up and down. He placed it in an upright position supported by two splints. The day after said treatment she was permitted to return to her home. The doctor continued to care for her for about three weeks during which time he removed the splints and called in a masseure to treat her. The last time the doctor saw the patient she was still complaining of pain in the shoulder and inability to properly use the arm, and the doctor advised her to again enter the hospital, but she refused, and he never saw her again.

Suit was thereafter instituted in which the claim was made that the doctor was negligent in treating the patient under the anesthetic. The charge was that he had so negligently manipulated her left shoulder as to over-stretch the arm and cause an injury to the motor and sensory nerves with a resultant stiffness of the fingers of the left hand and inability to use her left arm.

Two physical examinations were made after the suit had been commenced for the purpose of ascertaining the condition of the plaintiff; and the result of said examinations was that in the opinion of the examining doctors the woman suffered from no other ailments than a general arthritic condition which was in no way attributable to anything which the doctor had done.

The case was noticed for trial by the plaintiff's attorney but no steps were ever taken to place the case upon the Calendar for trial. After some time had elapsed an application was made by the defendant's attorney to dismiss the case for failure on the part of the plaintiff to diligently prosecute the same. The plaintiff's attorney rather than contest the motion agreed to discontinue the action, thereby terminating the matter finally in favor of the doctor.

NEWS NOTES

FEATURES OF THE ANNUAL MEETING

The forthcoming Annual Meeting of the Medical Society of the State of New York promises to be an unusual success. In a time in which bankers, public utilities' experts, even the judiciary are under criticism, it is a matter of great satisfaction to feel that the Medical Society of the State of New York is marching forward with increasing vigor and determination.

On Monday, April third, a Clinical Day, with clinics in the hospitals in the five boroughs, is being arranged under the Chairmanship of Dr. Peter Irving, assisted by Dr. Theodor Blum.

The House of Delegates will open at two p.m. in the Grand Ball Room of the Waldorf-Astoria Hotel, and a new feature of the Meeting of the House of Delegates will be an Inaugural Address by the incoming President, Dr. Frederick H. Flaherty, entitled "The Control of Medical Activities by the Medical Profession."

The afternoon of Monday will be given over to the deliberations of the House of Delegates, and at six-thirty p.m. the Dinner of the House of Delegates will take place in the Roof Garden of the Waldorf-Astoria, dress being informal. The dinner is open to any member of the Medical Society of the State of New York, the price of the dinner tickets being \$2.50 each. At seven-thirty, two items of medico-social importance will be presented: (1) Compulsory Health Insurance and the Panel System, by Dr. Emil Koffler, of New York City, and (2) The Participation of the Physician in Public Health Work, by Dr. Henry F. Vaughan, Commissioner of Health, Detroit, Mich. The salient features of these presentations will be illustrated by lantern slides.

Promptly at eight-forty-five p.m. the House of Delegates will reconvene and receive the findings and recommendations of the Special Committee appointed to consider the Report of the Committee on the Cost of Medical Care. This will be an Executive Session of the House of Deelgates and admission will be restricted to duly authenticated

Delegates.

The Scientific Sessions will begin on Tuesday morning and continue through Tuesday and Wed-

nesday, both morning and afternoon.

Dr. Arthur Bedell has arranged with the Chairmen and Secretaries of the Various Sections to present an unusually instructive, diversified and scientific program.

On Tuesday evening, April fourth, in the Grand Ball Room of the Waldorf-Astoria, at seven-thirty p.m., the Annual Meeting and Banquet of the Society will be held.

The program of the Annual Meeting to be held at the close of the Banquet is as follows:

- 1. Calling the meeting to order, Dr. Chas. Gordon Heyd.
- 2. Introduction of Dr. Samuel J. Kopetzky, Chairman of the Committee on Arrangements.
- 3. Introduction of Dr. Terry M. Townsend, President of the Medical Society of the County of New York, who will act as toastmaster.
- 4. Introduction of Dr. Edward H. Cary, President of the American Medical Association.
- 5. Introduction of Dr. Olin West, Secretary of the American Medical Association.
- 6. Introduction of the incoming President of the Medical Society of the State of New York, Dr. Frederick H. Flaherty.
- 7. Address, "The Decline of Medicine as an Art," Dr. Howard W. Haggard, Associate Professor of Physiology, Yale University, New Haven, Connecticut.
- 8. Address: "The Master in the House of Medicine," Alphonse M. Schwitalla, J.S., Ph.D., Dean, St. Louis University School of Medicine, St. Louis, Missouri.
- 9. Address, "The Medical Society of the State of New York, Our Responsibility and Our Obligation," Dr. Chas. Gordon Heyd.

10. 10:30 p.m.—Adjournment.

The Banquet will be brought to a close at ten-thirty p.m., when those wishing to dance will find the facilities available, with a tenpiece orchestra, on the Roof Garden of the Wal-The price of the tickets for the dorf-Astoria. Banquet is \$5 per person, and includes the Banquet and Dancing on the Roof Garden. Reservations for tickets for the Banquet should be made immediately so that table allotments may be made. Those purchasing tickets after March 28th cannot be assured of table allotments, although tables will be provided to take care of the guests. Tickets may be obtained from the Secretary of the Society, Dr. D. S. Dougherty, 2 East 103rd Street, New York City.

On Wednesday evening, April 5th, at 8 p.m., in the Grand Ball Room of the Waldorf-Astoria, the Medical Society of the State of New York introduces a new feature in having an Open Meeting to the public, with the following program; Dr. Chas. Gordon Heyd, Chairman:

1. The Community and the Physician, Olin

West, M.D., Chicago, Illinois.

2. What the Community Should Know:

(a) About Arthritis, Lewellys F. Barker. M.D., Baltimore, Md.

(b) About Goiter, Frank H. Lahey, M.D., Boston, Mass.

(e) About Appendicitis, Dean DeWitt Lewis, M.D., Baltimore, Md.

(d) About Diabetes, Elliott P. Joslin, M.D., Boston, Mass.

(e) About Heart Disease, William D. Strond, M.D., Philadelphia, Pa. (f) About Cancer, Burton J. Lee, M.D.,

New York City, N. Y.

(g) About Tuberenlosis, Linsly R. Williams, M.D., New York City, N. Y.

3. The Health of the State, Thomas Parran. Jr., M.D., Albany, N. Y., Commissioner, State Department of Health.

Admission to the Open Meeting will be by tickets. These may be obtained, gratis, from the Secretary of the Society, 2 East 103rd Street, New York City.

During the three days of the Meeting numerous radio broadcasting periods have been arranged for, with distinguished speakers from the City and outside of the City of New York.

A Publicity Department has been set up with an Advisory Committee on Publicity; and all publicity in connection with activities of the Medical Society of the State of New York shall be cleared through this office. The members of the Society presenting papers or matters of interest to the profession and to the community should see that a complete copy of their addresses or papers, or a full abstract of the same, is in the hands of the Publicity Department not later than Saturday. March 25th. The Society will look with disapprobation on any publicity by any member of the Society who has not utilized the Publicity Department for his public expressions.

> SAMUEL J. KOPETZKY, M.D., Chairman, Committee on Arrangements.

REFERENCE COMMITTEES OF THE HOUSE OF DELEGATES FOR 1933

The House of Delegates of the Medical Society of the State of New York is a legislative body and has adopted a method of procedure similar to that of the House of Representatives of the National Congress. The annual reports and the proposed motions are referred to Reference Commit-

(g) About Tuberculosis, Linsly R. Williams, M.D., New York City, N. Y.

3. The Health of the State, Thomas Parran, Jr., M.D., Albany, N. Y., Commissioner, State Department of Health.

Admission to the Open Meeting will be by tickets. These may be obtained, gratis, from the Secretary of the Society, 2 East 103rd Street, New York City.

During the three days of the Meeting numerous radio brondcasting periods have been arranged for, with distinguished speakers from the City and outside of the City of New York.

A Publicity Department has been set up with an Advisory Committee on Publicity; and all publicity in connection with activities of the Medical Society of the State of New York shall be cleared through this office. The members of the Society presenting papers or matters of interest to the profession and to the community should see that a complete copy of their addresses or papers, or a full abstract of the same, is in the hands of the Publicity Department not later than Saturday. March 25th. The Society will look with disapprobation on any publicity by any member of the Society who has not utilized the Publicity Department for his public expressions.

Samuel J. Kopetzky, M.D., Chairman, Committee on Arrangements.

REFERENCE COMMITTEES OF THE HOUSE OF DELEGATES FOR 1933

The House of Delegates of the Medical Society of the State of New York is a legislative body and has adopted a method of procedure similar to that of the House of Representatives of the National Congress. The annual reports and the proposed motions are referred to Reference Commit-

LEGISLATIVE BULLETIN NUMBER 8

March 3, 1933.

Hearings—March 14, Assembly Committee on Codes, Assembly Int. No. 63, Vaughan, Assembly Int. No. 181, Bernhardt: Antivivisection bills.

Action on Bills—Assembly Int. No. 772, Doyle, re. bichloride of mercury, has advanced to third reading in the Assembly and is being amended in revision.

Senate Int. No. 993, Twomey (Assembly Int. No. 1314—Streit), payment of fines, fees and penalties collected by Department of Education to be paid into the state treasury, to be postponed until 1935—has advanced to third reading in the Senate.

New Bills Introduced—Assembly Int. No. 1772—Schanzer, adds a new section to the Criminal Code, for proceedings when person arrested for certain crimes appears insane or to be a sex deviate. Referred to the Codes Committee.

* * *

There was a most important hearing yesterday before the joint Labor Committee on bills affecting the Workmen's Compensation Law. Lawrence appeared for the Society against the several occupational disease bills and in favor of the free choice bill. Commissioner Perkins, in her final appearance before a legislative committee, urged the enactment of one of the all-inclusive occupational disease bills. She said she felt the time has come when Industry should protect its employees against every manner of disablement that is incident to the occupation. course, Federated Labor was for the bills and a representative of the League of Women Voters spoke for them. Those opposed were Associated Industries, representatives of insurance companies and self-insurers, a representative of hotel associations, and a number of individual organizations. Dr. Curran, representing the New York Compensation Lawyers' Association, spoke against them, and Dr. Lawrence emphasized particularly the difficulty a physician would have in determining whether certain disabling conditions actually were due to the occupation or to what the employee might have done during the hours that he was not employed. He also pointed out the difficulties physicians would encounter in preventing malingering where there was a definite determination upon the part of the employee to do so, and also emphasized that Industry, to protect itself, would demand a careful physical examination of every employee prior to his being engaged; and the discovery of potential disabilities which might never materialize would, nevertheless, be recorded and might conceivably be the reason for his not being employed. Mr. Daly, General Secretary of Associated Industries, elaborated upon this statement and assured the committee that exactly what had been described by Dr. Lawrence would be followed and it would work a great hardship upon Labor that can and should be avoided.

* * *

The osteopathic bill has appeared in the Senate—Int. No. 1343—sponsored by H. L. O'Brien. File your protest immediately with your Senator and the Senate Committee on Public Education, whose personnel you will find in the "white book"; and also with the Majority and Minority Leaders, Senators Dunnigan and Fearon respectively. Remember that letters from prominent lay persons are usually very influential.

HARRY ARANOW, Chairman.

Action on Bills

Senate Int. No. 788—Berg, professional boards, was reported out and debated on the Senate floor, then laid aside to be taken up again next week.

Senate Int. No. 711—Byrne, lye bill, was amended and referred to the Senate Committee on Public Education.

Senate Int. No. 487—Esquirol, Health Department rules, was reported out of committee in the Senate and advanced to third reading.

Assembly Int, No. 705—Austin, Health Department rules, was reported out of committee in the Assembly and advanced to third reading.

Senate Int. No. 621—Quinn, employing experts in psychiatry, was reported out of committee in the Senate and advanced to third reading.

New Bills Introduced.

The osteopathy bill has appeared in the Senate, introduced by Mr. H. L. O'Brien by request; Senate Int. No. 1343. Referred to the Education Committee.

Senate Int. No. 1510—Esquirol; Assembly Int. No. 1970—Brownell, amends the Workmen's Compensation Law by placing in excepted employments inmates of, and other recipients of charitable aid from, a religious or charitable institution, who perform work in or for the institution in return for aid conferred. Referred to the Labor Committee.

Assembly Int. No. 1977—Mr. Nathanson has introduced an occupational disease bill which is identical with Assembly Int. No. 72 and Assembly Int. No. 130. Referred to the Labor Committee.

During the last week the Legislature concentrated entirely upon measures relating to the relief of the depression, and so there is very little action to be reported on bills that we have under observation. The chairmen should not, however, lose this opportunity of informing all of the legislators that we have recommended in our previous bulletins, regarding the pernicious bills that are before us.

Enclosed we are sending you a copy of a sheet of instructions which has been sent by the Teurporary Emergency Relief Administration (T. E. R. A.) to the welfare commissioners-county and town-of the state. See page 412. Heyd appointed a special committee with Dr. James N. Vander Veer as chairman, Dr. Hyzer Jones of Utica, Dr. Albert Swift of Syracuse, and Dr. Lawrence as secretary, to confer with Dr. Parray and Dr. Davis representing the T. E. R. A., at their request, to outline a program by which the T. E. R. A. might assist the public welfare officers in providing medical care for indigent persons. The outline enclosed is the result of this committee's work. Of course, this applies only in upstate counties; the five New York counties have a program of their own which is very similar but differs in some details.

We recommend, therefore, that you bring this to the attention of your County Society. It is definitely an extension of the public welfare work and, as you will observe, the commissioner of welfare will be reimbursed by the T. E. R. A. to the extent of 40 per cent of the amount expended in providing medical care. Each county will, naturally, work out a program of its own as to how the work shall be done and bills submitted and paid. This, however, must be clearly borne in mind-that physicians must receive authorization from the public welfare commissioner for all services before rendered, except emergencies. The welfare commissioner will have special forms upon which authorization will be made and physicians, if they intend to submit bills to the welfare officers for their services, must have the authorization endorsed by him and submit it with the bill. Authorization by telephone will not be sufficient, except in an emergency, and then must be supported by written authorization within twentyfour or forty-eight hours.

Dr. Wynkoop, chairman of the Onondaga County Public Relations Committee, is holding a conference this (Friday) afternoon to which Dr. Lawrence has been invited, for the purpose of developing plans for putting this program into operation in that county. It is recommended that every County Society, either at a regular or at a special meeting, or through one of its active committees, take up this outline with the welfare commissioners in order that there may be a complete understanding with regard to the manner in which the work will be done and compensation received. This is an exceedingly important matter. As was mentioned several times before, the administration of the Welfare Law will soon be a problem equally great, if not greater, than the administration of the Workmen's Compensation Law.

The last issue of our Journal carries the program for the next annual meeting of the State society. This promises to be one of the most worth while meetings we have ever had. We

should like particularly to call your attention to the program for the clinical day on Monday, April 3rd.

HARRY ARANOW, Chairman.

TEMPORARY EMERGENCY RELIEF ADMINISTRATION

Rules and Regulations Governing Medical Care to Home Relief Clients

The Temporary Emergency Relief Administration has issued the following rules and regulations governing medical care to home relief clients where medical care is provided on a fee basis:

1. A uniform procedure for authorization of medical care shall be established for each Welfare District. This procedure shall not be in conflict

with the following requirements.

All authorizations for medical care shall be issued in writing on the regular relief order blank, except that telephone authorization shall immediately be followed by such an order. This order shall authorize the doctor to provide medical care for a period not exceeding two weeks. Not more than ten visits, nor an expenditure of more than \$20.00 will be authorized by any such order. Medical care for more than two weeks shall be based only on a written renewal of the original authorization, such renewal not to be issued until after a re-investigation of the case in the home.

Medical care for prolonged illnesses, such as chronic asthma, chronic heart disease, chronic rheumatism, shall be authorized on an individual basis, and in general shall be limited to not more than one visit per week, and for a period not to exceed three months. In instances where more frequent visits seem to be indicated for a short period, additional authorization for such service shall be required.

2. In this emergency there is an increasing need for medical care, and a consequent need for the participation of an increasing number of physicians in medical care to recipients of Public Relief. It is recognized that it would be impossible with the funds available fully to compensate the physician for his professional serv-The Temporary Emergency Relief Administration will reimburse Public Welfare Districts the statutory forty per cent of authorized expenditures for medical care on the basis of not to exceed \$2.00 for a home visit, and \$1.00 for an office visit. The Administration will reimburse the statutory forty per cent of authorized payments for obstetrical services in the home on the basis of a fee of \$25.00, which fee shall include charges for delivery and a minimum of three prenatal office visits and the necessary postnatal care. Details of these services shall be submitted with the bill.

Special services shall be authorized on an individual basis, the general basis being a reduction of thirty-three and one-third per cent from the ordinary County fee schedule. A copy of the minimum County fee schedule shall be filed with the local Commissioner of Public Welfare and with the Director of Medical Care, Temporary Emergency Relief Administration.

- 3. Physicians who are providing medical service for Welfare patients shall submit monthly a separate bill for each patient, to the Commissioner of Public Welfare, and such bills shall be submitted not later than the 10th day of the month following the period of service. Payments made on the basis of retroactive authorizations will not be reimbursed by the Temporary Emergency Relief Administration.
- 4. Each bill shall be chronologically arranged and state the name, age, and address of the patient; the diagnosis, or a general indication of the nature of the illness; the nature of the treatment, i.e., in home, office, or special type of care; the dates on which service was rendered; and the status of the case at the end of the month (cured, sent to the hospital, needs further treatment, dead). Bills for medical care shall be accompanied by the original written authorization for such care.

Drugs

- 1. All prescriptions for necessary drugs and medicines shall be filled from the National Formulary or the United States Pharmacopæa. Proprietary remedies shall not be considered reimbursable by the Temporary Emergency Relief Administration.
- 2. Physicians providing authorized medical care to persons in receipt of public funds shall be encouraged to use a formulary which excludes expensive drugs where less expensive drugs can be used. When expensive medication is considered essential it may be authorized after consultation with the "Welfare" Committee of the local Medical Society.
- 3. Commissioners of Public Welfare should make trade agreements with druggists for uniform or reduced rates for prescriptions (for ex-

ample, the average prescription should not cost more than \$0.50 to \$0.75).

Medical Advice Should Be Available to Cammissianers of Public Welfare

1. The Medical Society of the State of New York has agreed to request each County Medical Society to appoint or designate a Committee to advise, at least monthly, with the local Commissioner of Public Welfare.

Whenever necessary the Commissioner of Public Welfare should consult this Committee concerning problems of medical care, such as:

(a) The reasonableness of any given bill for medical services.

(b) To investigate complaints made with regard to medical care.

(c) Any proposed change in policy with regard to provision of medical care.

(d) Principles to be followed in the allocation of cases to physicians.

2. Commissioners of Public Welfare should consult with this office with regard to any difficulties in the provision of medical care.

March 3, 1933.

TRI-STATE CONFERENCE

The twenty-second meeting of the Tri-State Conference of the officers of the medical societies of New York, New Jersey and Pennsylvania was held on Saturday, February 18, 1933, in the Hotel Pennsylvania, New York City, beginning at ten o'clock and continuing through a social luncheon at noon, and a brief session in the afternoon,

The subject of the medical service supplied to the workers in the Endicott-Johnson Company, manufacturers of shoes in the cities Johnson City and Endicott, a suburb of Binghamton, N. Y., was discussed by Dr. Howard W. Davis of Binghamton, New York, formerly Medical Director for the Company. The service is given to about 15,000 workers and their families, at a cost of about \$750,000 annually, of which \$175,000 are the salaries of about 30 full-time physicians connected with the service. The cost is met by a deduction of five per cent from the pay of each worker. Nearly all forms of medical and surgical service, including hospitalization, are given.

The medical service supplied by the Company

has a peculiar significance in that it may be compared with that given by private practitioners in the nearby city of Binghamton under almost the same conditions. The attitude of the two groups of practitioners toward each other is one of tolerance, with little evidence of jealousy or criticism between them.

Dr. Willard C. Rappleye, Dean of the College of Physicians and Surgeons, and Director of Study of the Commission on Medical Education, described the aims of the Commission and its lines of cooperation with physicians and their societies in preparing physicians to give the forms of medical service which the people require.

Dr. N. B. Van Etten of New York City, a member of the Committee on the Cost of Medical Care, described the progress made by physicians and their societies in meeting the problems which were discussed by the other speakers.

A valuable feature of the conference was the confidential opinions expressed by the speakers regarding recent experiments and demonstrations in medical service given by economic groups or by governmental agencies.

SULLIVAN COUNTY

At a special meeting of the Sullivan County Medical Society held February 15, 1933, at the Lenape Hotel in Liberty, 29 members heard a talk on undulant fever by Dr. M. R. French, of the department of research and laboratory of the State department of health. The paper was one of the best received that the society has listened to, probably due to the fact that Dr. French personally observed many cases of undulant fever in this district.

Following the talk, there was much discussion

of the subject, and Dr. French was beseiged by many questions.

After this there was a four-reel motion picture on the diagnosis and treatment of peptic ulcers. Dr. George F. Herben, president of the society presided at the meeting, which was preceded by a dinner.

The next meeting of the society will be held at the Lenape Hotel on March 1st.

HARRY GOLEMBE, M.D., Chairman af the Publicity Committee.

The last issue of our Journal carries the program for the next annual meeting of the State society. This promises to be one of the most worth while meetings we have ever had. We

should like particularly to call your attention to the program for the clinical day on Monday. April 3rd.

HARRY ARANOW, Chairman.

TEMPORARY EMERGENCY RELIEF ADMINISTRATION

MEDICAL COMMITTEE ON COMPENSATION ABUSES

The daily papers of February 13 carried news items on the appointment by Governor Lehman of a physicians' committee to study medical abuses in connection with the Workmen's Compensation Law, and to report plans for remedial legislation. The New York *Times* of February 13 says:

"The Governor's action is a sequel to one taken by his predecessor, Franklin D. Roosevelt, who referred to the Academy of Medicine a report rendered to him by a special committee, headed by Howard S. Cullman, setting forth the

abuses.

"Dr. Eugene H. Pool of New York City, one of five representatives of the New York Academy of Medicine, has been designated as chairman of the committee by Governor Lehman.

"The others representing the academy are: Drs. Frederick W. Bancroft, George Baehr, Adrian V. S. Lambert and Charles A. McKendree, all of New York City. Dr. Lambert has already been identified with the work as chairman of a subcommittee on medical problems of the Cullman committee.

"The members representing the New York State Medical Society are: Drs. David J. Kaliski of New York, Thomas McGoldrick of Brooklyn, F. M. Miller, Jr., of Utica, Harry R. Trick of Buffalo and Frederick S. Wetherell of Syracuse.

"The report of the Cullman committee to Governor Roosevelt in December was accompanied

by a leter jointly signed by Mr. Cullman and Dr. Lambert in which they informed the Governor that data assembled by the committee and included in the report furnished 'uncontroverted evidence of existing rackets' in workmen's compensation cases and urged that these should be eliminated at the earliest possible moment."

Commenting on this Committee the New York Herald Tribune of February 22, says:

"Governor Lehman's appointment of a distinguished medical committee to recommend specific remedies for abuses of the workmen's compensation law is assurance that a fight well begun is to be carried to a finish. There is always the danger that an inquiry suspended will lose its drive. Governor Lehman has guarded against this hazard by naming his committee of ten physicians representing the New York Academy of Medicine and the Medical Society of the State of New York to follow up conclusively the work thus far aecomplished. This committee, headed by Dr Eugene H. Pool, has as one of its members Dr Adrian V. S. Lambert, who was chairman of the Cullman subcommittee that so thoroughly prepared the ground. It lacks nothing of informed and high-minded purpose. There is reason to expect with Mr. Cullman that, 'by the intelligent application of responsible professional men to the problems involved,' in due course rackets and abuses may be eliminated by necessary legislative action."

MEDICAL ECONOMICS IN BUSINESS

The physician may not he classed as a financier by men of business, but the New York Times believes that business would be helped by the adoption of the economic methods of the physicians. The Times of February 10 says editorially:

"No more discerning suggestion has been made regarding the cause of our troubled state than that of Dr. Francis M. Pottenger, president of

the American College of Physicians:

"Were business concerns to adopt the altruistic spirit of physicians and take less profits or no profits at all from those who are unable to pay for goods, it would soon change the ruthless psychology which dominates modern economic life.

"The physician, obeying his own conscience and following the pledge of his profession, responds to every call within his skill and strength to answer. He does not pause to ask whether there will be even a reasonable profit for him or any compensation at all. It will be said that business cannot be carried on successfully on

any such basis, even if it has been found practicable in the professions, in the simpler life of earlier days and even in smaller communities today. But if the spirit to which Dr. Pottenger refers as characteristic of the medical profession, in its ministry to human ills without greed or even controlling thought of gain, were as pervasive in the field of business as in that of medicine, we might have escaped much of the economic misery we have been undergoing. What a Utopian world it would be!

"The profession has set an example in the family physician which is of value to the State. We say of the physician, as was said by Achilles of Machaon, son of Aesculapius, 'He is worth a host of us.' That is true of him not only in his skill but in his readiness to give to the community without sparing self and without greed of gain. The president of the American College of Physicians in his diagnosis has suggested a 'ruthless psychology' as the root of our economic trouble. But he has also written in his diagnosis the prescription of the remedy."

BOOK REVIEWS

THE CURATIVE VALUE OF LIGHT. By EDGAR MAYER, M.D. 12mo of 175 pages, illustrated. New York, D. Appleton and Company, 1932. Cloth, \$1.50.

Dr. Edgar Mayer in his new book, "The Curative Value of Light," writes as interestingly as he talks. He has full knowledge of his subject, as he so aptly shows.

In the early paragraphs he states it is mainly for the public's perusal. Taking this aspect of the subject he handles his matter remarkably well. He does not express any unfounded claims for this modality nor does he couch his language in too ultra scientific form for the layman.

The book is indeed valuable and instructive, and

should and will be read.

It will not harm the field of Light Therapy, but rather will stimulate interest, both medical and lay, because it so pointedly shows that Light Therapy is a powerful force and should be used by a patient only when directed and advised by a physician.

Hence it behooves every physician to read this book so that he can intelligently answer questions that will undoubtedly be asked concerning this form of therapy.

John J. Hauff.

FUNCTIONAL DISTURBANCES OF THE HEART. By HARLOW BROOKS, M.D. 12mo of 288 pages. Philadelphia, J. B. Lippincott Company, 1932. Fabrikoid, \$5.00. (Everyday Practice Series.)

This has been a most interesting monograph to review. Written "far distant from reference libraries," it perforce represents the personal views of its distinguished

Perhaps the first question to which we seek an answer relates to the basic character of "Functional Disturbances": are they purely reflex disorders of perverted physiologic function or have they an organic basis? Brooks states his belief frankly that in some instances physiology has trespassed over the border into pathology, and that physiologic changes may in some cases be of chemical or electrical type. Researches and more delicate differentiating laboratory staining methods of the past few years have indicated the former, as witness the study of the nuclear network of the cardiac cells in myocardial exhaustion (myocardia-asthenia).

The classification is as follows: 1. Effect of the emotions, 2. Anxiety angina, 3. Gastric distention and flatulence, 4. Cardiac exhaustion, 5. Early hyperthyroid heart, 6. Cardiac neuroses, 7. Paroxysmal tachycardia, and 8. Neurocirculatory asthenia.

The author is at his best in the two last subjects. Particularly is neurocirculatory asthenia handled with great understanding. His references to his military experiences are many, but discussion of this condition without consideration of the valuable observations in base and field hospitals would be impossible. The examination of recruits was in many ways an illuminating experience for most of us, but in no other disease was the lesson borne home as in neurocirculatory asthenia.

The ability of many patients with paroxysmal tachycardia to terminate their attacks by individualistic methods which are in some circumstances apparently absurd and entirely unreasonable is thoroughly discussed in citations of cases. We do not recall so interesting a clinical note as the author's description of the aged woman of 84, who, having had this disease since her sixteenth year, bounded out of bed on the sixth day of a lobar pneumonia to apply (and successfully so) her usual therapeutic measure for an attack which her nurses considered eardiac failure, fighting off both nurses with great vigor and then belligerently demanding their discharge for lack of intelligence.

References to the literature are few except in the last two chapters, and there is no bibliography. This accentuates the personal character of the volume, although we believe the value of a monograph is increased by the inclusion of those references and dates which help us to acquire a knowledge of the sequence of outstanding events in the scientific study of the disease or group of diseases under consideration. To be specific, this volume could have been enriched by giving the referenees to George Draper's physical types, Libman's pain sensitivity tests, Oppenheimer and Rothschild's proposal of the name neurocirculatory asthenia, the white vasomotor reaction of Ryan, and Mabon's discussion of early physical exhaustibility.

The book can be heartily recommended.

FRANK BETHEL CROSS.

THE SPUTUM. Its Examination and Clinical Significance. By RANDALL CLIFFORD, M.D. Oetavo of 167 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$4.00.

Examination of sputum is frequently required in the general hospital laboratory and is done by technicians or inexperienced physicians, who are badly in need of guidance as to the technique and interpretation of their findings. Dr. Clifford's book gives a clear, detailed, but not wordy description of the methods which have been found useful in the examinations of sputum and their diagnostic interpretation. The volume is well illustrated and should be welcomed by the laboratory workers.

M. A. Goldzieher.

CLINICAL ENDOCRINOLOGY OF THE FEMALE. By CHARLES MAZER, M.D., and LEOPOLD GOLDSTEIN, M.D. Octavo of 518 pages, illustrated. Philadelphia, W. B. Saundons Company 1932 Civil 2003 ders Company, 1932. Cloth, \$6.00.

The authors of this book have set out to present a clear, concise and instructive work on female endocrinology and have succeeded in a masterly way. Although the female sides are greatly stressed, the volume becomes, nevertheless, a classic in general endocrine studies.

The historical evolution of the two definitely isolated ovarian hormones, cestrian and progestin is vividly portrayed and the value of these hormones is carried through the most recent experimentations and developments. The processes of menstruation, gestation amenorrhea, etc., stand out clearly in their dependence upon these secretions and also upon the interrelated pituitary hormones.

The reader will find a thorough discussion of the acidophilic, basophilic and chromophobe cells of the anterior pituitary gland, the products of each group of cells and in general the role played by the pituitary organ upon sex, growth and metabolism. A similar illuminated study will carry him through the important, recent knowledge of the thyroid, adrenals, parathyroids, etc.

Of great merit are also the chapters on Menstrual Disorders and Their Therapy. In describing the treatment of these conditions x-ray application is properly evaluated. Pregnancy tests are fully described. Chapters on sterility, menopause and obesity complete this scholarly book.

Every practitioner of medicine should study this volume. Its contents will arouse in him interest in endocrinology and will be of great help to him in his daily JOSEPH S. BENDETSON. practièe.

Text-Book of Medicine. By various authors. Second edition, Edited by J. J. Conneare, M.D. Octavo of 1004 pages, illustrated. Baltimore, The Williams & Wilkins Company, (William Wood & Company), 1932. Cloth, \$8.00.

This is a practical, concise and fairly complete text-book of medicine, including a section on the more important diseases of the skin. In this edition there has been a complete revision of many of the subjects by the addition of the more modern advances in diagnosis and treatment. The physiological introductions, the pathology and treatment are well presented and should be of value to the medical student and general practioner of medicine. Henry Joachim.

DIABETES IN CHILDHOOD AND ADDLESCENCE, By PRISCILLA WHITE, M.D. Octavo of 236 pages, illustrated. Philadelphia, Lea & Febiger, 1932. Cloth, \$3.75.

The study and treatment of 750 juvenile diabeties represents an experience which one is rarely privileged to get. Dr. White, who is charged with the care of these young diabeties in Dr. Joslin's clinic, has had a larger experience with this type of case than any other single individual. This book is the result of her large and accumulated experience with the diabetic from birth through adolescence.

The book opens with a good concise historical review of this disease from the earliest Egyptian discoveries to the present time. In her chapter on etiology, she engages in an extensive discourse on the hereditary aspects of diabetes. She quotes a large literature, citing the familial incidence of the disease. She then attempts to apply to it the Mendelian law of inheritance with the role which dominant and recessive traits play in the transmission of hereditary characters. She finds it necessary to make theoretical corrections of her statistical data and draws her conclusions from rather speculative premises.

The chapter on pathogenesis and physiology is rather poor. Her sentences are frequently involved, her statements loose and often difficult of interpretation. To quote from page 74: "Subnormal function of the reservoirs for carbohydrate produce hyperglycemia and glycosuria. The treatment of diabetes will be made more difficult when such accidents occur, and conversely it is logical to believe that the management of the patient suffering from a disease in which the glucose netabolism of the body is interfered with will be improved by stimulations of the functions of these organs." And

so on fairly indefinitely.

The chapter on treatment represents a presentation of principles derived largely from the author's experience. There is little fundamental in it except that it displays a more progressive and freer use of carbohydrates than had previously been advocated by the Joslin clinic. The author follows a rather middle course and does not advocate the liberal diets of Sansum or Porges and Adlersberg. The range of carbohydrate values in her diets is between 100 and 200 grams. From the analysis of the table on page 117 it would appear that most of the diets contain carbohydrates in the lower range. There are no suggestions made to the reader regarding the indications for using any of the variations in this wide range of diets.

Dr. White analyzes the fasting blood sugars in her patients and classifies them on a chronological basis. She observes that since 1922, there is tendency toward a progressively increasing fasting blood sugar. Her speculative analysis of this data would indicate that height of the fasting blood sugar is in direct relation to the duration of the disease in any individual patient. The author engages in a considerable discourse on the clinical and prognostic significance of the fasting blood sugar. The reviewer finds it difficult to accept a number of titese concepts. One must remember that a liver subjected to a quantitatively greater degree of glyco-

genesis on a higher carbohydrate dict than on a more restricted one, will pour out its glycogen at a much greater rate when the patient is without an insulin effect. This condition usually exists in the early morning hours, and easily explains the high fasting blood sugars obtained in well-nourished diabetic children fed with a high carbohydrate diet. Dr. White's progressively increasing figures can be explained on the basis of a better nutritional state which she creates with her increasing liberality in her patients' diets.

The author has written an excellent chapter on the 10-year diabetic, a group of 72 juvenile patients studied since 1922—the time insulin was introduced. One is convinced of the remarkably good outlook which these

patients present.

On the whole this book represents a good contribution to the literature of diabetes, for it is a compilation of a unique mass of material both in quantity and biological variation.

WILLIAM S. COLLENS.

INTERNAL MEDICINE. Its Theory and Practice. Edited by John H. Musser, M.D. Octavo of 1316 pages, illustrated. Philadelphia, Lea & Febiger, 1932. Cloth, \$10.00.

The twenty-seven contributors to this volume are well known in American medicine, holding appointments in various medical schools and furnish a book in the modern trend, each being interested in a particular field. The articles in each group are condensed and usually each chapter begins with a discussion of the general features common to the group.

The standing of the writers insures authoritative statements and the book will be found very useful for reference.

WILLIAM E. MCCOLLOM.

THE SIGN OF BABINSKI, A Study of the Evolution on Cortical Dominance in Primates. By JOHN F, FULTON and ALLEN D. KELLER. Quarto of 165 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1932. Cloth, \$5.00.

In 1898, Babinski fully described the pathological plantar reflex. Since then, case studies have shown that the Babinski sign is indicative when positive, of injury to the overmidal pathways.

the pyramidal pathways.

The aims of the authors in presenting this book are several. First, a comparison of this reaction in the higher primates is made. In the monkey, the plantar reflex is observed following spinal transection, thoracic semisection of the spinal cord and removal of one cerebral hemisphere. In general, only when "the lower lumbar segments are completely freed from all forms of higher control, is the Babinski reflex seen in the monkey." Similar studies are made in the baboon, gibbon and chimpanzee. In these experiments, detailed surgical technique is outlined, for the authors wish to demonstrate the value of using the ligher primates in the study of problems of the C.N.S.

The next consideration is the study of the evolutionary background of the human nervous system. The significance of the difference in the Babinski response in the monkey and chimpanzee is dealt with. It means that in the higher primates only is the Babinski sign associated with Isolated destruction of the pyramidal pathways.

Two clinical implications are made; one with reference to traumatic cerebral diplegia, and secondly to Little's disease. In these the Babinski phenomena is positive.

The authors conclude with the observation, that conclusions from lower animals as applied to man are dangerous, unless "one compares corresponding lesions in a series of animals representing different stages of evolution of the central nervous system, it may then be safe, but only then, to predict the consequences of similar lesions of the human brain."

There is an appendix containing descriptions of anesthetics used and surgical technique. Also an extensive bibliography.

STANLEY S. LAMM.

HOSPITALIZATION INSURANCE IN NEW JERSEY

The Journal of the Medical Society of New Jersey for February contains the following account of a plan of insurance to secure hospital care in Newark:

"An important project affecting the doctors and hospitals of Essex County is under way. It is called the 'Hospital Service Plan' organized and advanced by the Hospital Council of Essex County. (Physicians and hospital managers are represented on the Council.)

"To increase the revenues and help support the hospitals a plan has been devised to insure wage earners against hospital charges for a 21-day period of illness in each year, at a cost of 85 cents per month. The Hospital Council, to effect the plan, has created a subsidiary body called the Associated Hospitals of Essex County, Inc.

"In consideration of \$10 a year, payable annually, semi-annually, or quarterly, or \$.85 per month, through voluntary pay-roll deductions, each payable in advance, the subscriber is entitled to participate in the benefits of the Hospital Service Plan of Associated Hospitals of Essex County, Inc., on the terms set forth below.

- "(1) The benefits hereinafter set forth are available to the subscriber immediately in the case of accident or emergency illness, and after fifteen days from date of this contract in other cases.
- "(2) Any hospital with which Associated Hospitals of Essex County, Inc., has a contract for such services in force at the time hospital service is applied for hereunder may be selected by the subscriber.
- "(3) The subscriber shall receive hospital care in semi-private accommodations, i.e., the patient shall occupy a bed in a room designed to serve

two or more private patients. If the subscriber prefers a single room, a credit of \$4 per day will be given on the price of the room selected.

- "(4) Hospital care includes bed and board, general nursing care, routine laboratory examinations, emergency and non-ambulatory x-rays, operating room, routine medications and dressings, general anesthesia when such service is supplied by the hospital, and all other customary routine treatment which may be prescribed by the physician during the period of hospitalization.
- "(5) Such hospital care and service will be furnished up to and including 21 days in any contract year, on one or more admissions.
- "(6) The benefits hereunder do not include services of the subscriber's attending physicians, surgeons, special nurses or their board.
- "(7) Service will be rendered only upon authorization and request by the subscriber's personal physician, who must be a member of a County Medical Society in New Jersey and/or acceptable to the hospital selected by the subscriber. During the period of hospitalization the subscriber must be under the treatment and care of such physician in accordance with his staff privileges at the hospital selected by the subscriber.

"The benefits included hereunder cover only the treatment and care of illness and injuries regularly accepted for treatment by the hospital selected by the subscriber, and do not in any event include obstetric cases, those provided for by Workmen's Compensation, quarantinable diseases, mental and nervous disorders, or illnesses usually treated at other than general hospitals of Essex County."

CERTIFICATION OF SPECIALISTS IN NEW JERSEY

The February number of the Journal of the Medical Society of New Jersey contains a tenpage account of the conference of county secretaries held in Trenton on November 2, 1932. The first subject discussed was the plan for the certification of specialists.

New Jersey has considered this subject more deeply than any other State, and a definite plan was adopted by the House of Delegates on June 15, 1932, as was described in this Journal of October 15, 1932, page 1216. The plan was described to the Secretaries' Conference by Presi-

dent John F. Hagerty, who then answered questions as follows:

"Have the various specialties been classified for this plan?"

Ans.: "Not yet, but that may have to be done

"In our Society, some of the younger men have taken objection to the classification of obstetricians thinking that might result in their losing patronage."

Ans.: "If one does exceptionally good obstetric

Have You Tried SARATOGA GEYSER

As An Acid Corrective?

S ARATOGA Geyser is a naturally carbonated mineral water, State owned and State bottled, containing the following solids:

Ammonium chlorid	61.17
Lithium chlorid	27.00
Potassium chlorid	233.81
Sodium cblorid	.2,511.61
Potassium broniid	32.00
Potassium iodid	
Sodium sulphate	
Sodium metaborate	trace
Sodium nitrate	trace

Sodium nitrite	trace
Sodium bicarbonate	2,206.54
Calcium bicarbonate	
Barium bicarbonate	
Strontium bicarbonate	trace
Ferrous bicarbonate	
Magnesium biearbonate	: 2874.71
Alumina	
Silica	

Total solids 7,856.87

Note: Results in milligrams per liter.

Saratoga Geyser, because of its natural carbonation and alkaline content, has been found extremely beneficial in many grades of mild acidosis, in aiding digestion, in various gastric neuroses and in the relief of hyperacidity. It is bottled just as it comes from the ground, under careful State supervision.

Upon written request, we will gladly send a complete analysis and a complimentary carton of Saratoga mineral waters for clinical tests, including 2 bottles of Geyser and 1 bottle each of Hathorn and Coesa.

(Continued from page 418) -

work and becomes a specialist, it is right after all that he should profit by his experience and knowledge."

"Do you not think it is rather important to have a classification of specialists? It seems to me that now-a-days there is a little feeling against making more specialties. It might not be a bad plan to limit the number in the beginning and then enlarge upon them."

Ans.: "There has been the objection raised in Essex County that we are really putting a premium upon specialism, and will in the end increase the number of specialists. I do not think that is a very valid objection."

"There are already in existence three classifications, any one of which could be used with satisfaction, I think: (1) that used by the A. M. A., in its provision for Section meetings; (2) that by the Congress of American Physicians and Surgeons, for a similar reason; and (3), that used by the American College of Surgeons. I think that in each instance the list includes 14 kinds of specialists."

"Is there an intention to recognize men who are established as specialists today? Of course, this plan is mainly to control specialism in the future, but in every community there are men today who are recognized as specialists though they may not have taken an examination or received any certificate."

Ans.: "That is the purpose of parts I read in reference to periods of service in hospitals, etc."

A special article by Dr. Hagerty also appears in the February Journal of the New Jersey State Society defending the plan. The Doctor says:

"The advocates of the plan were not given an opportunity to answer the arguments advanced by the opposition; many of them not justified by anything contained in the plan. I am, therefore, asking permission to publish the reasons for advocacy of this measure by the State Society, as read at the above-mentioned meetings, with comments on some of the statements made by its opponents.

"There is no law in any of our states designed to prevent anybody from put(ing himself forward as a specialist. You know also that the right to practice a specialty in these United States may be assumed by any one who has secured the degree of Doctor of Medicine (M.D.) and a state's license to practice general medicine—a term that is all-inclusive. Those statements are true, but, it is also perfectly well known to all of you that these rights and privileges have been abused, and that such abusive actions have resulted in criticism of the profession by the public, and in lessening that high regard for the profession which the public formerly held.

"Any licensed physician may hold himself out

(Continued on page 421-adv. xiii)

(Continued from page 420-adv. xii)

as a specialist, and in any particular line; and to add that he can and may, while practicing a specialty continue in general practice-and no organization has any right or power to interfere in the slightest degree with his lawful pursuit of either or both general practice and special practice. I have emphasized this because some persons have found fault with the "Plan" because it does not restrict specialists and hold them to their chosen, special class of work; while, at the same time others were finding fault because of their belief that an attempt was being made to prevent specialization. I might say here, too, that the choice of the word-control-was an unfortunate one, having, to some, a sinister meaning. It follows, from what I have explained, as to rights and privileges, that such things could not be done; and I assure you that there was no such wish on the part of the State Society, nor of anybody associated with development of the plan."

ENFORCING THE MEDICAL PRACTICE LAW IN NEW JERSEY

The February issue of the Journal of the Medical Society of New Jersey contains a list of 16 convictions obtained by the State Board of Medical Examiners for violations of the Medical Practice Laws. The list includes:

Druggists	4
Chiropractors	2
Osteopaths	2
Optomotrists	1
"Medicine Man"	1
Priest Physician	
Plain Quack	4
Midwife	I

Concerning one healer the Journal says:

"His method of practice consisted in taking a lock of hair from the head of the patient for the purpose of studying the vibrations of the bodygazing into a crystal-and telling patients that they were surrounded by evil influences which could only be warded off by wearing a shield which he would make, and by giving them medicine made from herbs, etc. In summing up the case, the Judge told the defendant that the days of witchcraft were passed and that there was no place in Cumberland County for a person who practiced the methods of treatment followed by the defendant. As the defendant could not pay the penalty, he was committed to jail for 100 days, the maximum penalty allowed by the statute.'

MEDICAL ECONOMICS IN NEBRASKA

The March number of the Nebraska State Medical Journal contains the following item which shows one reason that there has been a

(Continued on tage 422-adv. viv)

Psyllium seed as a bowel corrective has come into such general therapeutic use as a result of the pioneer work with Battle Creek Psylla, that the market is now flooded with a number of "cheap" brands which are contaminated with impurities that should never be allowed to enter the human stomach.

Before Psylla is pronounced flt for human use, the original seeds are subjected to a number of cleansing processes which include screening, sifting, sterilizing and fanning. In this way the dead, shriveled up seed is removed, as well as half-a-dozen kinds of waste material.

More Economical

So Psylla, dose for dose, has always been more economical. Now it is doubly so, because the price has been reduced materially.

NOTE: Psylla is not only sterilized, but an inner seal is placed on each can as a guaranty of its wholesomeness.

decrease of ten per cent in the membership of the State Medical Association during the past year:

"An esteemed correspondent writes that on receiving notice that his dues would be delinquent if not paid by February first, asked a farmer for ten dollars so he could pay his obligation to the medical association, whereupon the farmer produced the following amazing figures:

300	pound hog at 1½ cts	.\$4.50
50	bushels corn at 8 cts	4.00
25	bushels oats at 6 cts	1.50
	•	\$10.00

"The dues remained unpaid."

THE JOURNAL IN NEBRASKA

The annual report of Dr. F. A. Long, Editor of the Nebraska State Medical Association, contained in the Journal of March, comments on the Journal as follows:

"During the year 1932 the Nebraska State Medical Journal published a total of 548 reading pages—the equivalent of about one additional number of the Journal. Ordinarily we attempt to hold the number of pages each month to forty. Unusual conditions sometimes arise to compel the addition of four or eight pages to a few numbers, such as when the index, title page and list of membership are published in the December number.

"An unusual quantity of material the past year prompted the addition of more pages. This seemed the easier because our contract calls for a Journal of 64 inside pages and four cover pages and since the advertising dropped to about sixteen pages we felt freer to add more reading pages.

"If all contract space is not used we get a short rate credit, which in my eagerness to publish, I overlooked for some months.

"The report of the secretary-treasurer indicates that our advertising for 1932 amounted to \$1,278 less than it did for 1931 (25 per cent reduction). The report further shows a membership 99 less than for 1931, which gave the Journal Fund \$148.50 less membership subscription money. These two items of loss to the Fund amount to a total of \$1,426.50.

"The membership as reported to me by Secretary Adams a short time ago for 1932 was 1,083. It had dropped from 1,182 the year before. We may then reasonably expect a further drop for 1932 or, say 83, leaving us around 1,000 members for the current year. Our budget must be predicated on that basis.

"We have agreed on some economies for the immediate future in order to keep within a reason-

(Continued on page 423-adv. xv)

Please mention the JOURNAL when writing to advertisers

(Continued from page 422-adv 21v)

able budget and at the same time keep the Journal to the same high standard we like to see

"By keeping the rending matter in the Journal down to the minimum during the year we feel that we can save the equivalent of approximately \$299 for the year

"We furnish three cuts to any article in the Journal free of charge. A copper halftone 2/2/33/2, costs about \$4.10. We have been using copper halftones in the Journal, but find that zinc cuts will probably serve the purpose almost as well and have decided to use zinc cuts for this year. Zinc cuts are about half the price of the copper ones and we will in this way save about \$112.

"The past year we withdrew \$606.86 from in vestments and propose to continue the withdrawals from the Building and Lorn Associations during the coming year

"Mr Gene Huse of the Huse Publishing Covoluntarily offers to reduce the 1933 expense of publication of the Journal by seven and one-half per cent for one year which will amount to approximately \$305 64 for the year

"Dr R B Adams has agreed and requested that the amount paid him as business manager and out of which he hires his office asistant, be reduced to just the amount to be paid the office assistant, which will save another \$400

"If granted \$1.50 per member as previously we will be able to balance accounts and run without much loss to the Journal Fund"

The financial statement of the Journal is reported as follows

1932	1931
\$3,766 48	\$5,044 63
14 50	25 00
223 38	380 66

CHILD HEALTH IN NEBRASKA

The February number of the Nebraska State Medical Journal contains the following editorial on Child Health work in Nebraska:

"Nebraska has lagged behind most of the states in cooperating with the White House Conference on Child Welfare and Protection. This is so not because of any lack of desire on the part of the medical profession. It is the policy of the national organization to place at the head of the various state organizations the governor and the state officials who head the agencies that are directly concerned with child health and welfare. It has not been possible to secure such co-

operation in Nebraska with the result that the state lags behind most states of the union in following up the work as outlined by the national organization.

"The Woman's Voters League of Nebraska has sponsored the work and an organization has been effected that will start functioning in the near future. Doctors and nurses are particularly interested in that phase of the program which has to do with public health, the handicapped child and with medical service. An immense amount of valuable data was assembled by the national or-

(Continued from page 424-adv. xvi)

ganization but there remains for the Nebraska section the task of assembling data that concerns our own state. We want to know what is being done for the health and welfare of the children of Nebraska and to ascertain these facts the committee will look to the secretaries of the county medical societies. With this information in hand an educational campaign will be inaugurated that will be directed not alone to the lay public but to the doctors and nurses as well. It will be an educational venture free from the ballyhoo that too often accompanies such enterprises. If the committee has its way there will be no baby clinics, no 'one come all and help yourself' program offered to the public at the expense of the doctors and nurse.

"While the task is the direct responsibility of the pediatricians and obstetricians of the state there will be need for the cooperation of the medical and nursing profession as a whole if the largest good is to be derived and it is the earnest wish of the committee to have such cooperation."

An editorial in the March issue of the Nebraska State Medical Journal comments on Child Health as follows:

"Within the next year Nebraska expects to hold a conference which will discuss the results of state wide surveys on child needs in this state.

"The needs of the child will be discussed from various viewpoints, medical, educational and sociological.

"The pediatric section has now been partially organized and is proceeding with surveys. It is the desire of this section that every medical man in the community be enlisted in this work.

"The first problem to be solved is to make a complete survey of the needs of the child in various communities.

"Questionnaires will be sent out and it is hoped that each physician receiving one will take the time and interest to answer the questions as accurately as possible.

"The value of the survey depends entirely upon the cooperation of the medical profession. After the survey has been made and the needs of the children definitely determined, plans will be discussed for meeting these needs in a way most beneficial to the children, the medical profession and the community at large.

"With the present trend among various lay organizations to try out all sorts of bizarre experiments in the medical field it is necessary for the medical profession to endeavor to have a controlling hand in the development of these plans.

"We as physicians want every child in the state to be assured of the benefits of the best in medical practice. To do this we must know what is needed and make our plans accordingly."

ANTISEPTICS

Few classes of products have been exploited more than antiseptic agents. Many of these agents are capable of inhibiting bacterial growth and of destroying bacteria even in high dilution, but, in the final analysis, the physician's choice is likely to be based on more inflammation of the metatarsophalangeal hour to hour. See page xxiii.-Ao

than that. He thinks in terms of the safety of the product in daily use, the effectiveness of antibacterial action without harmful effect to the tissues, and its ability to stimulate cell regeneration and processes of repair. It is quite logical that he should.

Merthiolate, Lilly, is referred to as an organic mercury compound—sodium ethyl mercuri thiosalicylate. It is said to be a close approach to the ideal germicide and antiseptic. Not a single instance of mercurialism has been reported following its administration. It has been administered to human sub-jects in massive doses, intravenously, without demonstrable toxic effects. Its germicidal potency is said to be relatively uniform in water, brotli, serum, fibrin, and other media resembling tis-sue. It is in use as a biological pre-

As might be expected, Merthiolate, Lilly, is reported to have a wide range of usefulness in clinical medicine, and is offered by its manufacturers in a variety of convenient forms, through the drug trade. Eli Lilly and Company are pleased to supply detailed information on Merthiolate preparations to any member of the medical profession. Address the home office, at Indianapolis, Indiana.—Adv.

Priv. Dos. Oskar Stracker, "Zehende-formitäten" (Deformities of the toes). Dr. Stracker discusses the different forms of toe-deformities, their etiology and their treatment. In eases of ehronie

joint of the great toe, the author ca attention to the possibility of this co dition being easily mistaken for arth For its treatment he recommen massage and diathermy, and internaureeidin. In acute onset, local an phlogistic treatment with Antiphlog tine proved of great value. To less the pain when walking, it is recon mended that two strips of wood, plac at right angles, be attached to the so of the shoe in the area of the half.

VITAMIN "D"

Winter is a jailer who shuts us a in from the fullest vitamin D valof sunlight. The baby becomes virt ally a prisoner, in several senses: Fit of all, meterologie observations pro that winter sunshine in most section of the country averages 10 to 50 p eent less than summer sunshine. St ondly, the quality of the available su shine is inferior due to the greater d tance of the sun from the earth alte ing the angle of the sun's rays. Again the hour of the day has an importa bearing: At 8:30 A. M. there is average loss of over 31%, and 3:30 P. M., over 21%.

While neither Mead's Viosterol Oil 250 D nor Mead's 10 D Cod Liv Oil with Viosterol constitutes a su stitute for sunshine, they do offer ; effective, controllable supplement esp eially important because the only natt ral foodstuff that contains apprecial quantities of vitamin D is egg-yol Unlike winter sunshine, the vitamin value of Mead's antirachitic produc does not vary from day to day or fro

LIXIR BROMAURATE

(Elixir Gold Tribromide)

(Pre-eminently a neurosedative and antispasmodic)
Used essentially for the treatment of WHOOPING COUGH. Other
Therapeutic Indications: Bronchial asthma, chorea, migraine and petit
mal. IN FOUR-OUNCE ORIGINAL BOTTLES. A teaspoonful three or four times a day after meals.

Gold Pharmacal Company, New York

LEAD ENCEPHALOPATHY

A Clinico-Pathological Study

By N. W. WINKELMAN, M.D., PHILADELPHIA, AND JOHN L. ECKEL, M.D., BUFFALO

From the Wards and Laboratory of Neuropathology of the Philadelphia General Hospital and Temple University Medical School. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

Introduction

INTOXICATION with lead produces a group of cerebral symptoms known collectively under the term of lead encephalopathy. Because of the clinical importance and the increasing prevalence of the condition, and the fact that the mechanism of its action on the central nervous system is not well understood (Staemmler¹, Freifeld³, Aub, Fairhall, Minot and Roznikoff³), it was felt that a review of several cases might help towards elucidating it.

Among the nervous symptoms which occur in this condition, two, in particular, are important in throwing light on the mechanism of brain physiology. These are (1) convulsions and (2) mental symptoms.

The cause of convulsions in general has thus far eluded explanation (Lehman, Spatz and Wisbaum-Neubürger4). It is a rather interesting fact that, in convulsive states that are due to toxic causes, such as in uremia, eclampsia, and poisonings by heavy metals, the most constant change found in the brain is an endarteritis of the small vessels, with resultant areas of partial necrosis (verödungsherde). It is also significant that similar focal areas of loss of normal structure are to be found in true epilepsy (Spielmeyer,5 Uchimuras), even though the patient dies at a time when the endarteritic manifestations have completely disappeared, because in the chronic stages of this condition, the swollen lining cells shrink to below normal.

The second symptom which merits attention is the mental phenomena, as the result of poisoning with lead. The following symptoms are of great significance: headache, insomnia, tremors, dizziness, poor memory, lethargy, mild psychotic manifestations, advancing even to mania. The basic process in the determination of these symptoms is the action on the ganglion cells (Környey, Hassin*). Whether that action is directly on the cells themselves, or secondarily, through the small

blood vessels, or both, will be discussed in the interpretation of the pathologic findings in our cases. It is possible that analysis of similar processes will eventually give us a clew as to the mechanism of production of a mental picture. We know that acute and chronic alcoholism can produce mental symptoms, and we know that certain cortical changes occur in them. It is possible that in poisoning by different substances we will find the original points of attack, and it will be the means of furthering our knowledge of cortical physiology.

REPORT OF CASES

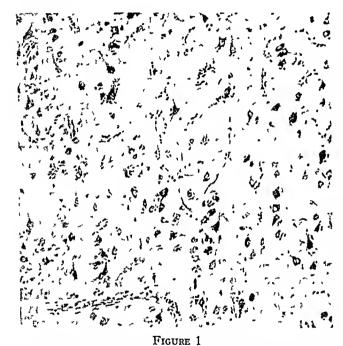

Case 1. 30-202. Summary: A colored male, of 31, a lead worker for several years, complained of gastric pains and occasional vomiting for one month before admission. He was admitted in a semiconscious condition. There were no palsies or muscle atrophies. There was a marked blue line about the gums. His blood showed secondary anemia, anisocytosis, poikilocytosis and numerous stippled red cells. He had two severe convulsions, and died within six hours after admission.

C. deS., a colored male, aged 31, was admitted to the Philadelphia General Hospital, service of Dr. David Riesman, August 21, 1930. and died the same day. He was admitted with the complaint of severe headache and showed disturbance of consciousness. The history stated that he had been working in lead in a metal foundry for a long time. About one month previous to admission, he laid off for one week because of gastric pain and vomitting. He then returned to work but did not feel well. The day of admission he was found in a semiconscious state in his room and was immediately removed to the hospital.

Examination on odmission revealed a partially conscious patient. He was fairly well nourished. The pupils were contracted and gave but slight reaction to light and in accommodation. The gums showed a marked blue line. The lungs were clear. The heart action was moderately irregu-

lar in rhythm with an occasional dropped beat, and a systolic murmur at the apex. Blood pressure was 130/60; pulse rate 40 to 60 per minute. The abdomen revealed general soreness, but no definite point of tenderness. The tendon reflexes were all hyperactive, but equal. There was an occasional abortive ankle clonus, with the suggestion of a Babinski on the right. There were no sensory or motor disturbances.

Laboratory Examination: Hemoglobin 10.7 gms.; red cell count 4,320,000; white cells 20,050, of which 87% were polynuclear cells. Stained smear revealed anisocytosis, poikilocytosis, achromia, stippled cells, normoblasts and megaloblasts. The urine was normal. The temperature varied from 98.8 to 99; the pulse from 40 to 60; respirations 22.

Case 1. Cortex, Toluidine blue stain—showing focal loss of ganglion cells with islands of comparatively normal cells between. Prominence of the small vessels is evident.

Course: One hour after admission he had a severe convulsion, with clonic and tonic contractures of both arms and legs, and frothing at the mouth. He then lapsed into unconsciousness, followed by another convulsive seizure, in three hours, in every way similar to the first. From this he did not regain consciousness, and died within six hours after admission.

Pathology: The heart weighed 340 gms. There was cloudy swelling and chronic fibroid myocarditis; the lungs revealed edema and pigmentary infiltration. All the bodily organs revealed congestion and marked pigmentary infiltration.

Gross Examination of the brain showed a small (1260 G.) anemic specimen, whose pia-arachnoid was only slightly thickened and edematous. The

basal vessels were small, thin walled, bluish and collapsed. There was a very moderate ventricular dilatation. There were no gross lesions in the cortex or subcortex.

Microscopic Examination: The meninges were very mildly fibrotic and slightly edematous, and contained an occasional group of cells of the pliagocytic type, that at times contained debris.

The Cortex: A general architectural disturbance could be seen at first glance. This was the result of three things: (1) There was a general decrease in the number of ganglion cells, and many that were left were only shadow cells (schattenzellen. Fig. 1). (2) While there was a general loss of ganglion elements, there were in addition small areas of incomplete softening (verödungsherde), where there was an almost complete loss of the neuronic elements and with but very feeble effort at gliosis or vascularization. These foci were usually very small, involved mainly the third cortical layer, were mainly around blood vessels and in vascular distributions, and gave the cortex a moth-eaten appearance. At times these acellular foci were so dense that they were confluent. (3) There was a definite increase in the glia, especially of the macroglia type. This was not a uniform process throughout the entire cortex, but varied from area to area. It was more marked in the marginal layer than elsewhere, and formed the so-called marginal gliosis. In places glia collections were to be found, especially in relation to the acellular foci. Cajal preparations brought out vividly, not only the general increase in glia, but also the focal increases, and particularly the marginal gliosis.

There was seen, in addition, a prominence of the small vessels, which was unusual (Fig. 2). Even the tiniest capillaries were brought out, and the larger capillaries also had swollen lining cells, with little lateral buddings as evidence of the new vessel formation.

There was not a uniform affection of the ganglion cells throughout the cortex, but one was impressed by the fact that even adjacent to areas of intense involvement of the ganglion cells, there were small foci where they were absolutely normal. This was a different condition than prevails, e.g., in pneumonia, where the ganglion cells are uniformly cloudy and swollen.

There was no uniform type of ganglion cell change; there appeared, in general, to be a slow liquefactive change, and a gradual disappearance. At only one place was there found a glia rosette, such as has been described in the literature as of frequent occurrence.

Stains for fat showed a moderate increase of lipoid in nearly all the ganglion cells, and particularly around the blood vessels, but not to the excessive degree that is seen in other conditions.

Edema was not a feature of the cortex. The large vessels were unaffected to any great extent

FIGURE 2

Case 1 Small focal area of cell destruction (Schallenzellen) without reactive gliosis, surrounded by comparatively normal ganglion cells

Case 2. 24-212. Summory: A young man, aged 25, who worked as an acetylene operator, melting lead in the hold of his ship, developed weakness, loss of weight, colicky pains in the abdomen, plus marked anemia, all rather acutely, three weeks prior to admission to the hospital Two weeks later he developed convulsions and died He showed secondary anemia, stippling of

red cells and blue line on the gums

L S, a white male, aged 25, was admitted to the Philadelphia General Hospital, service of Dr. Ross Patterson, November 18, 1924, and died November 19, 1924. He was an acetylene torch operator, and was engaged in melting lead in the hold of a vessel for a little less than a year. Three weeks before admission he complained of colicky pains around the umbilious, associated with headache, blurred vision, weakness of his hands and feet. For this he laid off for a week or so, and drank quite heavily. Two days before admission he became confused and weak. went to bed with his clothes on. He then became lethargic and could not talk coherently There was a history of epileptiform seizures during a period of several months

Examination on admission revealed a well nourished young man who was comatose, without the odor of alcohol on his breath. He had frequent convulsive seizures, beginning with twitching of the right lower extremity, which spread over the entire body. The pupils were round, equal and reacted normally. The eye movements were normal; the eyecrounds showed no choking and no hemorrhages. There was a bline line about the gums.

the upper and lower extremities were present, equal and active. There was no Babinski and no clonus. He became increasingly comatose, his convulsions became more frequent, and he died

Laboratory Examination: Hemoglobin 70%, red blood cells 2,900,000; white count 17,000, of which 82% were polynuclear eells. The spinal fluid was clear and gave a negative Wassermann Urea nitrogen 62 mgm; uric acid 2.8 mgm., sugar 125 mgm. The red cells showed marked stippling.

Pathology: A cloudy swelling of all the internal organs was present with pigmentary infiltra-

tion.

Gross Examination of the brain revealed notli-

Microscopic Examination: The meninges showed a very definite thickening as the result of edema and fibrosis. There was present, within the meshes of the pia occasional abnormal elements. These were of two types. The most frequent consisted of phagocytic cells that contained greenish and bluish pigment. These were large cells with abundant cytoplasm and a comparatively small eccentric nucleus. The other type of cell present was the lymphocyte. These were by far in the great minority, and it was only occasionally that this type of cell could be definitely established.
